

Vivado Design Suite Tutorial

Partial Reconfiguration

UG947 (v2019.1) June 12, 2019

Revision History

The following table shows the revision history for this document.

Section	Revision Summary
06/12/2019 Version 2019.1	
General updates	Validated for 2019.1 release. Updated various links.
Lab 6: Partial Reconfiguration Controller IP for UltraScale Devices	Corrected references to new lab.
12/20/2018 Version 2018.3	
Lab 7: Partial Reconfiguration Controller IP for UltraScale+ Devices	Added new lab.
04/27/2018 Version 2018.1	
General updates	Validated for 2018.1 release. Updated menu commands.
Lab 1: 7 Series Basic Partial Reconfiguration Flow	Rewrote lab to work with updated design files.
Overview	New section in Lab 1.
Step 4: Assembling and Implementing the Design	Added a step for setting board and part variables.
Lab 2: UltraScale Basic Partial Reconfiguration Flow	Rewrote lab to work with updated design files.
Overview	New section in Lab 2.
Step 4: Assembling and Implementing the Design	Added a step for setting board and part variables.
Run the PR Configuration Analysis Report	Added information on including submodule IP in the PR Configuration Analysis Report.

Overview

This tutorial covers the Partial Reconfiguration (PR) software support in Vivado® Design Suite release 2018.3.

[Lab 1: 7 Series Basic Partial Reconfiguration Flow](#) and [Lab 2: UltraScale Basic Partial Reconfiguration Flow](#) step through basic information about the current Partial Reconfiguration (PR) design flow, example Tcl scripts, and show results within the Vivado integrated design environment (IDE). You run scripts for part of the lab and work interactively with the design for other parts. You can also script the entire flow, and a completed script is included with the design files. These labs focus specifically on the software flow from RTL to bitstream, demonstrating how to process a Partial Reconfiguration design. Lab 2 also applies to UltraScale+™ devices.

[Lab 3: Partial Reconfiguration Project Flow](#) steps you through the project flow within the Vivado IDE, from establishing the design using the Partial Reconfiguration Wizard to synthesis, iteration runs, and then iterating the design. [Lab 4: Vivado Debug and the PR Project Flow](#) also walks you through the project flow, but includes adding IP, debug cores, and debugging through the Vivado Hardware Manager.

[Lab 5: Partial Reconfiguration Controller IP for 7 Series Devices](#), [Lab 6: Partial Reconfiguration Controller IP for UltraScale Devices](#), and [Lab 7: Partial Reconfiguration Controller IP for UltraScale+ Devices](#) are designed to show the fundamental details and capabilities of the Partial Reconfiguration Controller (PRC) IP in the Vivado Design Suite. Managing partial bitstreams is one of the new design requirements introduced by PR: designers plan for when partial bitstreams are required, where they are stored, how they are delivered to the configuration engine, and how the static design behaves before, during and after the delivery of a new partial bitstream. The PRC IP is designed to help users solve these challenges.

Hardware and Software Requirements

This tutorial requires that the 2018.3 Vivado Design Suite software release or later is installed. A Partial Reconfiguration license is required to run the PR software tools in the Vivado Design Suite. If necessary, request access by sending an email to pr_access@xilinx.com for a 30-day evaluation license. A valid corporate or university email address is required.

The labs in this tutorial document target eight different Xilinx development platforms. Unless specifically noted, production silicon and production boards are required to match the instructions in each lab. For Operating Systems support, see the *Vivado Design Suite User Guide: Release Notes, Installation, and Licensing (UG973)* for a complete list and description of the system and software requirements.

Tutorial Design Description

Designs for the tutorial labs are available as a zipped archive on the Xilinx website. Each lab in this tutorial has its own folder within the zip file. To access the tutorial design files:

1. Download the [Reference Design Files](#) from the Xilinx website.
2. Extract the zip file contents to any write-accessible location.

Lab 1: 7 Series Basic Partial Reconfiguration Flow

The sample design used throughout this tutorial is called `led_shift_count_7s`. The design targets the following Xilinx development platforms:

- KC705 (xc7k325t)
- VC707 (xc7vx485t)

- VC709 (xc7vx690t)
- AC701 (xc7a200t)

This design is very small, which helps minimize data size and allows you to run the tutorial quickly, with minimal hardware requirements.

Lab 2: UltraScale Basic Partial Reconfiguration Flow

The sample design used throughout this tutorial is called `led_shift_count_us`. The design targets the following Xilinx development platforms:

- KCU105 (xcku040)
- VCU108 (xcvu095)
- KCU116 (xcku5p)
- VCU118 (xcvu9p)

Lab 3 Partial Reconfiguration Project Flow

The sample design used throughout this tutorial is called `pr_project`. It is a modified version of the `led_shift_count` design used in Lab 1, modified to include two shift instances instead of one counter and one shifter. This change helps illustrate that a Partition Definition applies to all instances of a partition type. The design targets the following Xilinx development platforms:

- KC705 (xc7k325t)
- VC707 (xc7vx485t)
- VC709 (xc7vx690t)
- KCU105 (xcku040)
- KCU116 (xcku5p)
- VCU108 (xcvu095)
- VCU118 (xcvu9p)

Lab 4: Vivado Debug and the PR Project Flow

The sample design used is called `pr_project_debug`. The design targets the following Xilinx development platforms:

- KCU105 (xcku040)
- VCU108 (xcvu095)
- KCU116 (xcku5p)
- VCU118 (xcvu9p)

Lab 5: Partial Reconfiguration Controller IP for 7 Series Devices

The sample design used throughout this tutorial is called `prc_7s` and is based on the design used in Lab 1. The design targets the following Xilinx development platforms:

- KC705 (xc7k325t)
- VC707 (xc7vx485t)
- VC709 (xc7vx690t)

Lab 6: Partial Reconfiguration Controller IP for UltraScale Devices

The sample design used throughout this tutorial is called `prc_us`. The design targets an xcvu095 device for use on the VCU108 demonstration board, Rev 1.0, and is based on the design used in Lab 2.

Lab 7: Partial Reconfiguration Controller IP Tutorial Design

The sample design used throughout this tutorial is called `prc_usp` and is based on the design used in Lab 6. The design targets the KCU116 and VCU118 demonstration boards.

Lab 1: 7 Series Basic Partial Reconfiguration Flow

Overview

This lab introduces the basic PR flow for 7 series devices. First, you will use a script to individually synthesize the static module and each reconfigurable design module variant. Then in the IDE, you will constrain the location of the reconfigurable modules (RM) using Pblocks and implement the initial configuration of the design. Next, you will implement alternate configurations by locking the static portion of the design, updating the reconfigurable modules with a variant, and re-running implementation. Finally, you will verify that each implemented RM is compatible with the static portion of the design and, if compatible, generate bitstreams.

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see Tutorial Design Description.
 2. Navigate to `\led_shift_count_7s` in the extracted files. The `led_shift_count_7s` data directory is referred to in this lab as the `<Extract_Dir>`.
-

Step 2: Examining the Scripts

Start by reviewing the scripts provided in the design archive. The files `run_pr.tcl` and `advanced_settings.tcl` are located at the root level. The `run_pr.tcl` script contains the minimum required settings to run partial reconfiguration. The `advanced_settings.tcl` contains default flow settings and should only be modified by experienced users.

The Main Script

In the `<Extract_Dir>`, open `run_pr.tcl` in a text editor. This is the master script where you define the design parameters, design sources, and design structure. This is the only file you have to modify to compile a complete Partial Reconfiguration design. Find more details regarding `run_pr.tcl`, `advanced_settings.tcl`, and the underlying scripts in the `README.txt` located in the `Tcl_HD` subdirectory.

Note the following details in `run_pr.tcl`:

- Under **Define target demo board**, you can select one of many demonstration boards supported for this design.
- Under **flow control**, you can control what phases of synthesis and implementation are run. In the tutorial, only synthesis is run by the script; implementation, verification, and

bitstream generation are run interactively. To run these additional steps via the script, set the flow variables (e.g., `run.prImpl`) to **1**.

- The **Output Directories** and **Input Directories** set the file structure expected for design sources and results files. You must reflect any changes to your file structure here.
- The **Top Definition** and **RP Module Definitions** sections allow you to reference all source files for each part of your design. Top Definition covers all sources needed for the static design, including constraints and IP. The RP Module Definitions section does the same for Reconfigurable Partitions (RP). Identify each RP and list all Reconfigurable Module (RM) variants for each RP.
 - This design has two Reconfigurable Partitions (`inst_shift` and `inst_count`), and each RP has two module variants.
- The **Configuration Definition** sections define the sets of static and reconfigurable modules that make up a configuration.
 - This design has two configurations, `Config_shift_right_count_up_implement` and `Config_shift_left_count_down_import`. You can create more configurations by adding RMs or by combining existing RMs.

The Supporting Scripts

Underneath the `Tcl_HD` subdirectory, several supporting Tcl scripts exist. The scripts are called by `run_pr.tcl`, and they manage specific details for the Partial Reconfiguration flow. Provided below are some details about a few of the key PR scripts.

CAUTION! Do not modify the supporting Tcl scripts.

- `step.tcl`
Manages the current status of the design by monitoring checkpoints.
- `synthesize.tcl`
Manages the details regarding the synthesis phase.
- `implement.tcl`
Manages the details regarding the module implementation phase.
- `pr_utils.tcl`
Manages the details regarding the top-level implementation of a PR design.
- `run.tcl`
Launches the actual runs for synthesis and implementation.
- `log_utils.tcl`
Handles report file creation at key points during the flow.

Remaining scripts provide details within these scripts (such as other `*_utils.tcl` scripts) or manage other Hierarchical Design flows (such as `hd_utils.tcl`).

Step 3: Synthesizing the Design

The `run_pr.tcl` script automates the synthesis phase of this tutorial. Five iterations of synthesis are called, one for the static top-level design and one for each of four Reconfigurable Modules.

3. Open the Vivado Tcl shell:
 - On Windows, select the Xilinx Vivado desktop icon or **Start > All Programs > Xilinx Design Tools > Vivado 2018.x > Vivado 2018.x Tcl Shell**.
 - On Linux, simply type, `vivado -mode tcl`.
4. In the shell, navigate to the `<Extract_Dir>` directory.
5. If you are using a target demonstration board other than the KC705, modify the `xboard` variable in `run_pr.tcl`. Valid alternatives are the VC707, VC709 and AC701 boards.
6. Run the `run_pr.tcl` script by entering:

```
source run_pr.tcl -notrace
```

After all five passes through Vivado Synthesis have completed, the Vivado Tcl shell remains open. You can find log and report files for each module, alongside the final checkpoints, under each named folder in the `Synth` subdirectory.

TIP: In the `<Extract_Dir>` directory, multiple log files have been created:

- `run.log` shows the summary as posted in the Tcl shell window
 - `command.log` echoes all the individual steps run by the script
 - `critical.log` reports all critical warnings produced during the run
-

Step 4: Assembling and Implementing the Design

Now that the synthesized checkpoints for each module, plus top, are available, you can assemble the design.

You will run all flow steps from the Tcl Console, but you can use features within the IDE (such as the floorplanning tool) for interactive events.

TIP: Copy and paste commands directly from the tutorial to avoid redundant effort and typos in the Vivado IDE. Copy and paste only one full command at a time. Note that some commands are long and span multiple lines.

1. Open the Vivado IDE. You can open the IDE from the open Tcl shell by typing `start_gui` or by launching Vivado with the command `vivado -mode gui`.
2. Navigate to the `<Extract_Dir>` directory if you are not already there. The `pwd` command can confirm this.

3. Set variables that help with copying commands from this document into the Tcl Console. Select the part and board you are targeting for this lab, and apply them in Vivado:

```
set part "xc7k325t-ffg900-2"
set board "kc705"
```

```
set part "xc7vx485t-ffg1761-2"
set board "vc707"
```

```
set part "xc7vx690t-ffg1761-2"
set board "vc709"
```

```
set part "xc7a200t-fbg676-2"
set board "ac701"
```

4. Create an in-memory design by issuing the following command in the Tcl Console:

```
create_project -in_memory -part $part
```

5. Load the static design by issuing the following command:

```
add_files ./Synth/Static/top_synth.dcp
```

6. Load the top-level design constraints by issuing these commands:

```
add_files ./Sources/xdc/top_io_$board.xdc
```

```
set_property USED_IN {implementation} [get_files ./Sources/xdc/top_io_$board.xdc]
```

Selecting the `top_io_$board` version of the available xdc file loads the pin location and clocking constraints, but does not include floorplan information. The `top_$board` version includes pin location, clocking and floorplanning constraints.

7. Load the first two synthesis checkpoints for the shift and count functions by issuing these commands:

```
add_files ./Synth/shift_right/shift_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_shift} [get_files ./Synth/shift_right/shift_synth.dcp]
```

```
add_files ./Synth/count_up/count_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_count} [get_files ./Synth/count_up/count_synth.dcp]
```

The `SCOPED_TO_CELLS` property ensures that the proper assignment is made to the target cell. See this [link](#) in *Vivado Design Suite User Guide: Using Constraints (UG903)* for more information.

8. Link the entire design together using the `link_design` command:

```
link_design -mode default -reconfig_partitions {inst_shift inst_count} -part $part -top top
```

At this point a full configuration is loaded, including static and reconfigurable logic. Note that the Flow Navigator pane is not present while you are working in non-project mode.

TIP: Place the IDE in floorplanning mode by selecting **Layout > Floorplanning**. Make sure the Device view is visible.

9. Save the assembled design state for this initial configuration:

```
write_checkpoint -force ./Checkpoint/top_link_right_up.dcp
```

Step 5: Building the Design Floorplan

Next, create a floorplan to define the regions that will be partially reconfigured.

1. Select the `inst_count` instance in the Netlist pane. Right-click and select **Floorplanning > Draw Pblock**, or select the **Draw Pblock** toolbar button , and draw a tall narrow box on the left side of the X0Y3 clock region. The exact size and shape do not matter at this point, but keep the box within the clock region.

Make sure that the Pblock is selected in the Device View before continuing.

Figure 1: Pblock for the inst_count Reconfigurable Partition

Although this Reconfigurable Module only requires CLB resources, it also includes RAMB16, RAMB32, or DSP48 resources if the box encompasses those types. This allows the routing resources for these block types to be included in the reconfigurable region. The General tab of the Pblock Properties pane can be used to add these if needed. The Statistics tab shows the resource requirements of the currently loaded Reconfigurable Module.

2. In the Properties pane, select the checkbox for **RESET_AFTER_RECONFIG** to utilize the dedicated initialization of the logic in this module after reconfiguration completes.
3. Repeat steps 1 and 2 for the `inst_shift` instance, this time targeting the right side of clock region X1Y1. This Reconfigurable Module includes block RAM instances, so the resource type must be included. If omitted, the RAMB details in the **Statistics** tab are shown in red.

Figure 2: Pblock for the inst_shift Reconfigurable Partition

4. Run Partial Reconfiguration Design Rule Checks by selecting **Reports > Report DRC**. You can uncheck **All Rules** and then check **Partial Reconfiguration** to focus this report strictly on PR DRCs.

Figure 3: Partial Reconfiguration Design Rule Checks (DRCs)

One or two DRCs are reported at this point, and there are two ways of resolving them. For this lab, you will use one method for `inst_shift` and the other for `inst_count`.

The first DRC is an error, HDPR-10, reporting that `RESET_AFTER_RECONFIG` requires Pblock frame alignment.

- To resolve the first DRC error, make sure that the height of the Pblock aligns with the clock region boundaries. Using the Pblock for `inst_shift`, stretch the top and bottom edges to match the clock region boundaries of X1Y1 as shown in the figure below. See that the shading of the Pblock is now more uniform.

Figure 4: Pblock for the aligned `inst_shift` Reconfigurable Partition

The other possible DRC is a warning, HDPR-26, reporting that a left or right edge of a reconfigurable Pblock terminates on an improper boundary. Left or right edges must not split interconnect (INT) columns. More information on this requirement can be found in the *Vivado Design Suite User Guide: Partial Reconfiguration* (UG909), in the section entitled Reconfigurable Partition Pblock Sizes and Shapes.

- To manually avoid this DRC warning, zoom into the upper or lower corner on the reported edge of `inst_shift` (or `inst_count`, if `inst_shift` did not report an issue) to see where the violation occurred. Move this edge left or right one column, as shown by the yellow arrows in Figure 5, so it lands between two resource types (CLB-CLB or CLB-RAMB, for example) instead landing between CLB-INT or BRAM-INT.

Figure 5: Adjusting the Edges of a Reconfigurable Pblock

7. Run the PR DRCs again to confirm that the errors and warnings that you have addressed have been resolved for the `inst_shift` instance.

An alternative to manually adjusting the size and shape of reconfigurable Pblocks is to use the `SNAPPING_MODE` feature. This feature automatically adjusts edges to align with legal boundaries. It will make the Pblock taller, aligning with clock region boundaries, if the `RESET_AFTER_RECONFIG` feature is selected. It makes the Pblock narrower, adjusting left and/or right edges as needed. Note that the number and type of resources available are altered if `SNAPPING_MODE` makes changes to the Pblock.

8. Select the Pblock for `inst_count` in the Device window, and in the **Properties** tab of the Pblock Properties pane, change the value of `SNAPPING_MODE` from OFF to ROUTING (or ON).

Note that the original Pblock does not change, but the shading behind it does. The adjustments to the Pblock needed for it to conform to PR rules are done automatically, without modifying your source constraints.

9. Run the PR DRCs once again to confirm that all errors have been resolved. Advisory messages may still be reported, especially if the Pblock is located near the edge of the device.

10. Save these Pblocks and associated properties:

```
write_xdc ./Sources/xdc/top_all.xdc
```

This exports all the current constraints in the design, including those imported earlier from `top_io_$board.xdc`. These constraints can be managed in their own XDC file or managed within a run script (as is typically done with `HD.RECONFIGURABLE`).

Alternatively, the Pblock constraints themselves can be extracted and managed separately. A Tcl proc is available to help perform this task.

a. First source the proc which is found in one of the Tcl utility files:

```
source ./Tcl_HD/hd_utils.tcl
```

b. Then use the `export_pblocks` proc to write out this constraint information:

```
export_pblocks -file ./Sources/xdc/pblocks.xdc
```

This writes the Pblock constraint information for both Pblocks in the design. Use the `-pblocks` option to select only one if desired.

Now that the floorplan is established, the next step is implementing the design.

Step 6: Implementing the First Configuration

In this step, you place and route the design and prepare the static portion of the design for reuse with new Reconfigurable Modules.

Implementing the Design

1. Optimize, place, and route the design by issuing the following command:

```
opt_design
```

This is the point at which the Partial Reconfiguration license is checked. If you have a valid license, you see this message:

```
Feature available: PartialReconfiguration
```

If you have no license with the `PartialReconfiguration` feature, contact your local Xilinx sales office for more information. Evaluation licenses are available.

```
place_design
```

```
route_design
```

After both `place_design` and `route_design`, examine the state of the design in the Device view (See Figure 6). One thing to note after `place_design` is the introduction of Partition Pins. These are the physical interface points between static and reconfigurable logic. They are anchor points within an interconnect tile through which each I/O of the Reconfigurable Module must route. They appear as white boxes in the placed design view.

For `pblock_shift`, they appear in the top of that Pblock, as the connections to static are just outside the Pblock in that area of the device. For `pblock_count`, they appear outside the user-defined region, as SNAPPING_MODE vertically collects more frames to be added to the Reconfigurable Partition.

Figure 6: Partition Pins within Placed Design

11. To find these partition pins in the GUI easily:
 - a. Select the Reconfigurable Module (for example, `inst_shift`) in the Netlist pane.
 - b. Select the **Cell Pins** tab in the Cell Properties pane.
12. Select any pin to highlight it, or use **Ctrl+A** to select them all. The Tcl equivalent of the latter is:

```
select_objects [get_pins inst_shift/*]
```
13. Use the **Routing Resources** toolbar button  to toggle between abstracted and actual routing information, and to change the visibility of the routing resources themselves. All nets in the design are fully routed at this point.

Figure 7: Close-up of First Configuration Routed

Saving the Results

14. Save the full design checkpoint and create report files by issuing these commands:

```
write_checkpoint -force Implement/Config_shift_right_count_up_implementation/top_route_design.dcp
report_utilization -file Implement/Config_shift_right_count_up_implementation/top_utilization.rpt
report_timing_summary -file Implement/Config_shift_right_count_up_implementation/top_timing_summary.rpt
```

15. [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

```
write_checkpoint -force -cell inst_shift Checkpoint/shift_right_route_design.dcp
write_checkpoint -force -cell inst_count Checkpoint/count_up_route_design.dcp
```

TIP: When running `run_pr.tcl` to process the entire design in batch mode; design checkpoints, log files, and report files are created at each step of the flow.

At this point, you have created a fully implemented partial reconfiguration design from which you can generate full and partial bitstreams. The static portion of this configuration is used for all subsequent configurations. To isolate the static design, remove the current Reconfigurable Modules. Make sure routing resources are enabled, and zoom in to an interconnect tile with partition pins.

16. Clear out Reconfigurable Module logic by issuing the following commands:

```
update_design -cell inst_shift -black_box
update_design -cell inst_count -black_box
```

Issuing these commands results in many design changes as shown in the figure below:

- The number of Fully Routed nets (green) decreases.
- `inst_shift` and `inst_count` now appear in the Netlist view as empty.

Figure 8: The `inst_shift` module before (top) and after (bottom) `update_design -black_box`

17. Issue the following command to lock down all placement and routing:

```
lock_design -level routing
```

Because no cell was identified in the `lock_design` command, the entire design in memory (currently consisting of the static design with black boxes) is affected. All routed nets are now displayed as locked, as indicated by dashed lines in the figure below. All placed components changed from blue to orange to show they are also locked.

Figure 9: Close-up of Static-Only Design with Locked Routing

18. Issue the following command to write out the remaining static-only checkpoint:

```
write_checkpoint -force Checkpoint/static_route_design.dcp
```

This static-only checkpoint is used for future configurations.

19. Close this design before moving on to the next configuration:

```
close_project
```

Step 7: Implementing the Second Configuration

Now that the static design result is established and locked, and you can use it as context for implementing further Reconfigurable Modules.

Implementing the Design

1. Create a new in-memory design by issuing the following command in the Tcl Console:

```
create_project -in_memory -part $part
```

2. Load the static design by issuing the following command:

```
add_files ./Checkpoint/static_route_design.dcp
```

3. Load the second two synthesis checkpoints for the shift and count functions by issuing these commands:

```
add_files ./Synth/shift_left/shift_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_shift} [get_files ./Synth/shift_left/shift_synth.dcp]
```

```
add_files ./Synth/count_down/count_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_count} [get_files ./Synth/count_down/count_synth.dcp]
```

4. Link the entire design together using the link_design command:

```
link_design -mode default -reconfig_partitions {inst_shift inst_count} -part $part -top top
```

At this point, a full configuration is loaded. This time, however, the static design is routed and locked, and the reconfigurable logic is still just a netlist. Place and route from here only applies to the RM logic.

5. Optimize, place and route the new RMs in the context of static by issuing these commands:

```
opt_design
```

```
place_design
```

```
route_design
```

The design is again fully implemented, now with the new Reconfigurable Module variants. The routing is a mix of dashed (locked) and solid (new) routing segments, as shown below.

Figure 10: Second Configuration Routed, Showing Locked and New Routes

Saving the Results

6. Save the full design checkpoint and report files by issuing these commands:

```
write_checkpoint -force Implement/Config_shift_left_count_down_import/top_route_design.dcp
report_utilization -file Implement/Config_shift_left_count_down_import/top_utilization.rpt
report_timing_summary -file Implement/Config_shift_left_count_down_import/top_timing_summary.rpt
```

7. [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

```
write_checkpoint -force -cell inst_shift Checkpoint/shift_left_route_design.dcp
write_checkpoint -force -cell inst_count Checkpoint/count_down_route_design.dcp
```

At this point, you have implemented the static design and all Reconfigurable Module variants. Repeat this process for designs that have more than two Reconfigurable Modules per Reconfigurable Partition.

Step 8: Examining the Results with Highlighting Scripts

With the routed configuration open in the IDE, run some visualization scripts to highlight tiles and nets. These scripts identify the resources allocated for partial reconfiguration, and are automatically generated.

1. In the Tcl Console, issue the following commands from the <Extract_Dir> directory:

```
source hd_visual/pblock_inst_shift_AllTiles.tcl

highlight_objects -color blue [get_selected_objects]
```
2. Click somewhere in the Device view to deselect the frames (or enter `unselect_objects`), then issue the following commands:

```
source hd_visual/pblock_inst_count_AllTiles.tcl

highlight_objects -color yellow [get_selected_objects]
```

The partition frames appear highlighted in the Device view, as shown in [Figure 11](#).

Figure 11: Reconfigurable Partition Frames Highlighted

These highlighted tiles represent the configuration frames that are sent to bitstream generation to create the partial bitstreams. As shown above, the `SNAPPING_MODE` feature adjusted all four edges of `pblock_count` to account for `RESET_AFTER_RECONFIG` and legal reconfigurable partition widths.

The other “tile” scripts are variations on these. If you had not created Pblocks that vertically aligned to the clock region boundaries, the `FrameTiles` script would highlight the explicit Pblock tiles, while the `AllTiles` script extends those tiles to the full reconfigurable frame height. Note that these leave gaps where unselected frame types (for example: global clocks) exist.

The `GlitchTiles` script is a subset of frame sites, avoiding dedicated silicon resources; the other scripts are more informative than this one.

3. Close the current design:

```
close_project
```

Step 9: Generating Bitstreams

Verifying Configurations

RECOMMENDED: Before generating bitstreams, verify all configurations to ensure that the static portion of each configuration match identically, so the resulting bitstreams are safe to use in silicon. The PR Verify feature examines the complete static design up to and including the partition pins, confirming that they are identical. Placement and routing within the Reconfigurable Modules is not checked, as different module results are expected here.

1. Run the `pr_verify` command from the Tcl Console:

```
pr_verify Implement/Config_shift_right_count_up/Implement/top_route_design.dcp
Implement/Config_shift_left_count_down/import/top_route_design.dcp
```

If successful, this command returns the following message.

```
INFO: [Vivado 12-3253] PR_VERIFY: check points
Implement/Config_shift_right_count_up/top_route_design.dcp and
Implement/Config_shift_left_count_down/top_route_design.dcp are compatible
```

By default, only the first mismatch (if any) is reported. To see all mismatches, use the `-full_check` option.

2. Close the project:

```
close_project
```

Generating Bitstreams

Now that the configurations have been verified, you can generate bitstreams and use them to target your selected demonstration board.

Note: *The first configuration implements `shift_right` and `count_up`. The second configuration implements `shift_left` and `count_down`.*

3. First, read the first configuration into memory:

```
open_checkpoint Implement/Config_shift_right_count_up_implement/top_route_design.dcp
```

4. Generate full and partial bitstreams for this design. Be sure to keep the bit files in a unique directory related to the full design checkpoint from which they were created.

```
write_bitstream -force -file Bitstreams/Config_RightUp.bit
```

```
close_project
```

Notice that three bitstreams have been created:

- o `Config_RightUp.bit`
This is the power-up, full design bitstream. The four shift LEDs on the right will shift right and the four count LEDs on the left will count up.
- o `Config_RightUp_pblock_inst_shift_partial.bit`
This is the partial bit file for the `shift_right` module.
- o `Config_RightUp_pblock_inst_count_partial.bit`
This is the partial bit file for the `count_up` module that causes the count LEDs to count up.

IMPORTANT: When generated by a single call to `write_bitstream`, the names of the bit files currently do not reflect the name of the Reconfigurable Module variant to clarify which image is loaded. The current solution uses the base name given by the `-file` option and appends the Pblock name of the reconfigurable cell. It is critical to provide enough description in the base name to be able to identify the reconfigurable bit files clearly. All partial bit files have the `_partial` postfix.

Using `run_pr.tcl` to process the entire design through bitstream generation uses a different technique for generating the bitstreams. Opening a routed design checkpoint issues multiple calls to `write_bitstream`, which gives you more control over naming bitstreams and allows for different options (such as bitstream compression) to be applied to full versus partial bitstreams. For example, the names configured in the `advanced_settings.tcl` script are:

- o `Config_shift_right_count_up_implement_full.bit`
This is the power-up, full design bitstream.
- o `pblock_shift_shift_right_partial.bit`
This is the partial bit file for the `shift_right` module.

- o `pblock_count_count_up_partial.bit`
This is the partial bit file for the `count_up` module.

5. Generate full and partial bitstreams for the second configuration, again keeping the resulting bit files in the appropriate folder.

```
open_checkpoint Implement/Config_shift_left_count_down_import/top_route_design.dcp
write_bitstream -force -file Bitstreams/Config_LeftDown.bit
close_project
```

Similarly, you see three bitstreams created, this time with a different base name.

6. Generate a full bitstream with grey boxes, plus blanking bitstreams for the Reconfigurable Modules. Blanking bitstreams can be used to “erase” an existing configuration to reduce power consumption.

```
open_checkpoint Checkpoint/static_route_design.dcp
update_design -cell inst_count -buffer_ports
update_design -cell inst_shift -buffer_ports
place_design
route_design
write_checkpoint -force Checkpoint/Config_greybox.dcp
write_bitstream -force -file Bitstreams/config_greybox.bit
close_project
```

The base configuration bitstream has no logic for either reconfigurable partition. The `update_design` commands here insert constant drivers (ground) for all outputs of the Reconfigurable Partitions, so these outputs do not float. The term *grey box* indicates that the modules are not completely empty with these LUTs inserted, as opposed to black boxes, which would have dangling nets in and out of this region. The `place_design` and `route_design` commands ensure they are completely implemented.

Step 10: Partially Reconfiguring the FPGA

The `count_shift_led` design targets one of four demonstration boards. The current design supports the KC705, VC707, VC709 and AC701 boards, revisions Rev 1.0 and Rev 1.1.

Configuring the Device with a Full Image

1. Connect the board to your computer via the Platform Cable USB and power on the board.
2. From the main Vivado IDE, select **Flow > Open Hardware Manager**.
3. Select **Open a new hardware target** on the green banner. Follow the steps in the wizard to establish communication with the board.
4. Select **Program device** on the green banner, and select the target device. Navigate to the `Bitstreams` folder to select `Config_RightUp.bit`, then click **OK** to program the device.

You should now see the bank of GPIO LEDs performing two tasks. Four LEDs are performing a counting-up function (MSB is on the left), and the other four are shifting to the right. Note the amount of time it took to configure the full device.

***Note:** The AC701 demonstration board only has a 4-bit LED bank. This design will show either the shift function or the count function at one time. To switch between the shift and count functions, toggle the switch 1 on the GPIO DIP switch (SW2).*

Partially Reconfiguring the Device

At this point, you can partially reconfigure the active device with any of the partial bitstreams that you have created.

5. Select **Program device** on the green banner again. Navigate to the `Bitstreams` folder to select `Config_LeftDown_pblock_inst_shift_partial.bit`, then click **OK** to program the device.

The shift portion of the LEDs changed direction, but the counter kept counting up, unaffected by the reconfiguration. Note the much shorter configuration time.

6. Select **Program device** on the green banner again. Navigate to the `Bitstreams` folder to select `Config_LeftDown_pblock_inst_count_partial.bit`, then click **OK** to program the device.

The counter is now counting down, and the shifting LEDs were unaffected by the reconfiguration. This process can be repeated with the `Config_RightUp` partial bit files to return to the original configuration, or with the blanking (grey box) partial bit files to stop activity on the LEDs (that will stay on).

Conclusion

This concludes Lab 1. In this lab, you:

- Synthesized a design bottom-up to prepare for partial reconfiguration implementation
- Created a valid floorplan for a partial reconfiguration design
- Created two configurations with common static results
- Implemented these two configurations, saving the static design to be used in each
- Created checkpoints for static and reconfigurable modules for later reuse
- Examined framesets and verified the two configurations
- Created full and partial bitstreams
- Configured and partially reconfigured an FPGA

Lab 2: UltraScale Basic Partial Reconfiguration Flow

Overview

This lab introduces the basic PR flow for UltraScale devices. First, you will use a script to individually synthesize the static module and each reconfigurable design module variant. Then in the IDE, you will constrain the location of the reconfigurable modules (RM) using Pblocks and implement the initial configuration of the design. Next, you will implement alternate configurations by locking the static portion of the design, updating the reconfigurable modules with a variant, and re-running implementation. Finally, you will verify that each implemented RM is compatible with the static portion of the design and, if compatible, generate bitstreams.

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see the Tutorial Design Description.
 2. Navigate to `\led_shift_count_us` in the extracted files. The `led_shift_count_us` data directory is referred to in this lab as the `<Extract_Dir>`.
-

Step 2: Examining the Scripts

Start by reviewing the scripts provided in the design archive. The files `run_pr.tcl` and `advanced_settings.tcl` are located at the root level. The `run_pr.tcl` script contains the minimum required settings to run partial reconfiguration. The `advanced_settings.tcl` contains default flow settings and should only be modified by experienced users.

The Main Script

In the `<Extract_Dir>`, open `run_pr.tcl` in a text editor. This is the master script where you define the design parameters, design sources, and design structure. This is the only file you have to modify to compile a complete Partial Reconfiguration design. Find more details regarding `run_pr.tcl`, `advanced_settings.tcl`, and the underlying scripts in the `README.txt` located in the `Tcl_HD` subdirectory.

Note the following details in this `run_pr.tcl`:

- Under **Define target demo board**, you can select one of many demonstration boards supported for this design.
- Under **flow control**, you can control what phases of synthesis and implementation are run. In the tutorial, only synthesis is run by the script; implementation, verification, and

bitstream generation are run interactively. To run these additional steps via the script, set the flow variables (e.g., `run.prImpl`) to **1**.

- The **Output Directories** and **Input Directories** set the file structure expected for design sources and results files. You must reflect any changes to your file structure here.
- The **Top Definition** and **RP Module Definitions** sections let you reference all source files for each part of your design. **Top Definition** covers all sources needed for the static design, including constraints and IP. The **RP Module Definitions** section does the same for Reconfigurable Partitions (RP). Identify each RP and list all Reconfigurable Module (RM) variants for each RP.
 - This design has two Reconfigurable Partitions (`inst_shift` and `inst_count`), and each RP has two module variants.
- The **Configuration Definition** sections define the sets of static and reconfigurable modules that make up a configuration.
 - This design has two configurations defined within the master script: `config_shift_right_count_up_implement` and `config_shift_left_count_down_import`.
 - You can create more configurations by adding RMs or by combining existing RMs.

The Supporting Scripts

Underneath the `Tcl_HD` subdirectory, several supporting Tcl scripts exist. The scripts are called by `run_pr.tcl`, and they manage specific details for the Partial Reconfiguration flow. Provided below are some details about a few of the key PR scripts.

CAUTION! Do not modify the supporting Tcl scripts.

- `step.tcl`
Manages the current status of the design by monitoring checkpoints.
- `synthesize.tcl`
Manages all the details regarding the synthesis phase.
- `implement.tcl`
Manages all the details regarding the module implementation phase.
- `pr_utils.tcl`
Manages all the details regarding the top-level implementation of a PR design.
- `run.tcl`
Launches the actual runs for synthesis and implementation.
- `log_utils.tcl`
Handles report file creation at key points during the flow.

Remaining scripts provide details within these scripts (such as other `*_utils.tcl` scripts) or manage other Hierarchical Design flows (such as `hd_utils.tcl`).

Step 3: Synthesizing the Design

The `run_pr.tcl` script automates the synthesis phase of this tutorial. Five iterations of synthesis are called, one for the static top-level design and one for each of four Reconfigurable Modules.

1. Open the Vivado Tcl shell:
 - o On Windows, select the Xilinx Vivado desktop icon or **Start > All Programs > Xilinx Design Tools > Vivado 2018.x > Vivado 2018.x Tcl Shell**.
 - o On Linux, type: `vivado -mode tcl`.
2. In the shell, navigate to the `<Extract_Dir>` directory.
3. If you are using a target demonstration board other than the KCU105, modify the `xboard` variable in `run_pr.tcl`. The alternative for this lab is the VCU108 board.
4. Run the `run_pr.tcl` script by entering:

```
source run_pr.tcl -notrace
```

After all five passes through Vivado Synthesis have completed, the Vivado Tcl shell is left open. You can find log and report files for each module, alongside the final checkpoints, under each named folder in the `Synth` subdirectory.

TIP: In the `<Extract_Dir>` directory, multiple log files have been created:

- `run.log` shows the summary as posted in the Tcl shell window
- `command.log` echoes all the individual steps run by the script
- `critical.log` reports all critical warnings produced during the run.

Step 4: Assembling and Implementing the Design

Now that the synthesized checkpoints for each module, plus top, are available, you can assemble the design.

You will run all flow steps from the Tcl Console, but you can use features within the IDE (such as the floorplanning tool) for interactive events.

TIP: Copy and paste commands directly from this document to avoid redundant effort and typos in the Vivado IDE. Copy and paste only one full command at a time. Note that some commands are long and therefore span multiple lines.

1. Open the Vivado IDE. You can open the IDE from the open Tcl shell by typing `start_gui` or by launching Vivado with the command `vivado -mode gui`.

2. Navigate to the `<Extract_Dir>` directory if you are not already there. The `pwd` command can confirm this.

3. Set variables that help with copying commands from this document into the Tcl Console. Select the part and board you are targeting for this lab, and apply them in Vivado:

```
set part "xcku040-ffva1156-2-e"
set board "kcu105"
```

```
set part "xcvu095-ffva2104-2-e"
set board "vcu108"
```

```
set part "xcku5p-ffvb676-2-e"
set board "kcu116"
```

```
set part "xcvu9p-flga2104-2L-e"
set board "vcu118"
```

4. Create an in-memory design by issuing the following command in the Tcl Console:

```
create_project -in_memory -part $part
```

5. Load the static design by issuing the following command:

```
add_files ./Synth/Static/top_synth.dcp
```

6. Load the top-level design constraints by issuing these commands:

```
add_files ./Sources/xdc/top_io_$board.xdc
```

```
set_property USED_IN {implementation} [get_files ./Sources/xdc/top_io_$board.xdc]
```

Selecting the `top_io_$board` version of the available xdc file loads the pin location and clocking constraints, but does not include floorplan information. The `top_$board` version includes pin location, clocking and floorplanning constraints.

7. Load the first two synthesis checkpoints for the shift and count functions by issuing these commands:

```
add_file ./Synth/shift_right/shift_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_shift} [get_files ./Synth/shift_right/shift_synth.dcp]
```

```
add_file ./Synth/count_up/count_synth.dcp
```

```
set_property SCOPED_TO_CELLS {inst_count} [get_files ./Synth/count_up/count_synth.dcp]
```

The `SCOPED_TO_CELLS` property ensures that the proper assignment is made to the target cell. See this [link](#) in *Vivado Design Suite User Guide: Using Constraints (UG903)* for more information.

8. Link the entire design together using the `link_design` command:

```
link_design -mode default -reconfig_partitions {inst_shift inst_count} -part $part -top top
```

At this point a full configuration is loaded, including static and reconfigurable logic. Note that the Flow Navigator pane is not present while you are working in non-project mode.

TIP: Place the IDE in floorplanning mode by selecting **Layout > Floorplanning**. Make sure the Device view is visible.

9. Save the assembled design state for this initial configuration:

```
write_checkpoint ./Checkpoint/top_link_right_up.dcp
```

Step 5: Building the Design Floorplan

Next, create a floorplan to define the regions for partial reconfiguration.

1. Select the `inst_count` instance in the Netlist pane. Right click and select **Floorplanning > Draw Pblock** and draw a tall narrow box on the left side of the upper left corner of the device. The exact size and shape do not matter at this point, but keep the box within the clock region.

Make sure that the Pblock is selected in the Device View before continuing.

Figure 12: Pblock for the `inst_count` Reconfigurable Partition

Although this Reconfigurable Module only requires CLB resources, also include RAMB16, RAMB32, or DSP48 resources if the box encompasses those types. This allows the routing resources for these block types to be included in the reconfigurable region. The **General** tab of the Pblock Properties pane can be used to add these if needed. The **Statistics** tab shows the resource requirements of the currently loaded Reconfigurable Module.

- Repeat the previous step for the `inst_shift` instance, this time targeting clock region below the first. This Reconfigurable Module includes block RAM instances, so the resource type must be included. If omitted, the RAMB details in the **Statistics** tab will be shown in red.

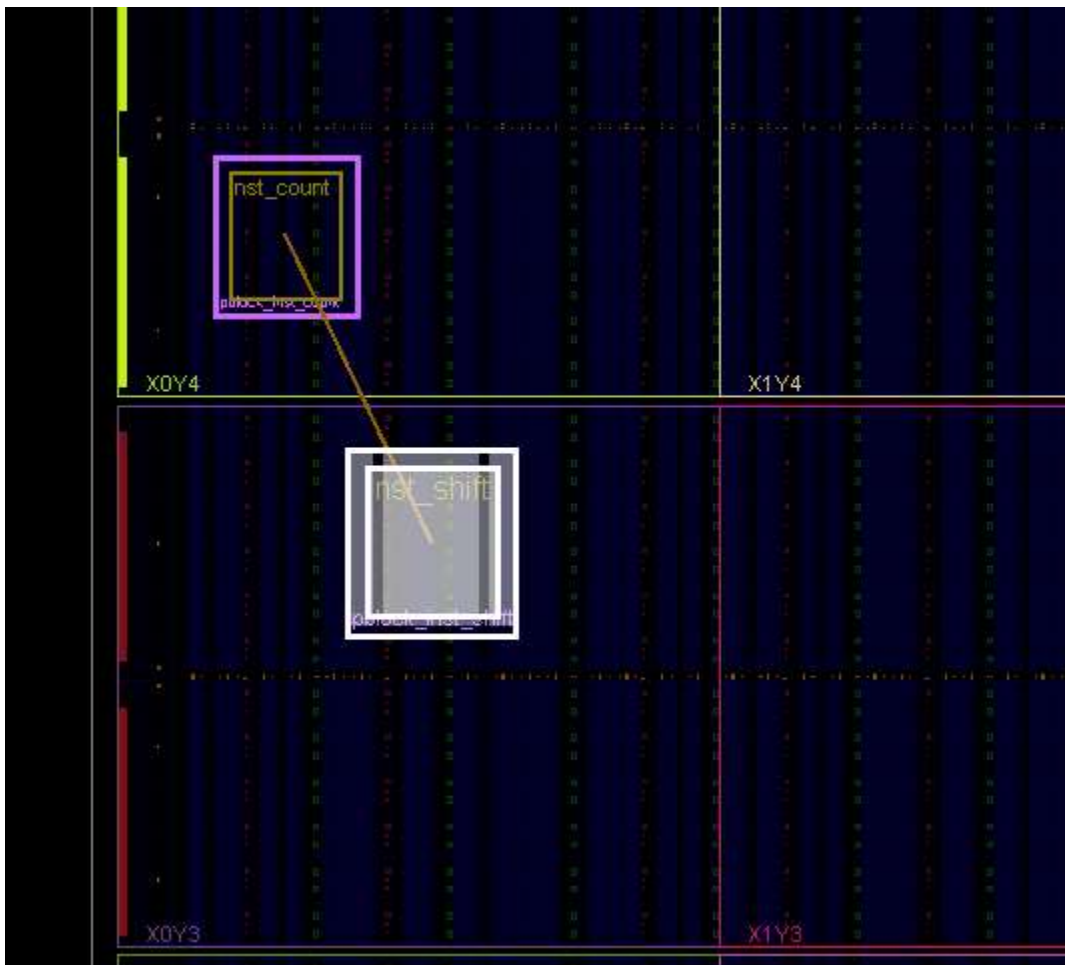

Figure 13: Pblock for the `inst_shift` Reconfigurable Partition

- Run Partial Reconfiguration Design Rule Checks by selecting **Reports > Report DRC**. You can uncheck **All Rules** and then check **Partial Reconfiguration** to focus this report strictly on PR DRCs.

Figure 14: Partial Reconfiguration Design Rule Checks (DRCs)

No DRC errors should be reported, as long as the `inst_shift` pblock includes RAMB18 and RAMB36 resources. Advisory messages may still be reported, especially if the Pblock is located near the edge of the device. Note that for both Pblocks, `SNAPPING_MODE` is set to ON, as reported in the **Properties** tab of the Pblock Properties pane. This is always enabled for all UltraScale devices given the fine granularity of programmable units in this architecture.

4. Save these Pblocks and associated properties:

```
write_xdc ./Sources/xdc/top_all.xdc
```

This exports all the current constraints in the design, including those imported earlier from `top_io_$board.xdc`. These constraints can be managed in their own XDC file or managed within a run script (as is typically done with `HD.RECONFIGURABLE`).

Alternatively, the Pblock constraints themselves can be extracted and managed separately. A Tcl proc is available to help perform this task.

- a. First source the proc which is found in one of the Tcl utility files:

```
source ./Tcl_HD/hd_utils.tcl
```

- b. Then use the `export_pblocks` proc to write out this constraint information:

```
export_pblocks -file ./Sources/xdc/pblocks.xdc
```

This writes the Pblock constraint information for both Pblocks in the design. Use the `-pblocks` option to select only one if desired.

Step 6: Implementing the First Configuration

In this step, you place and route the design and prepare the static portion of the design for reuse with new Reconfigurable Modules.

Implementing the Design

1. Optimize, place, and route the design by issuing the following commands:

```
opt_design
```

This is the point at which the Partial Reconfiguration license is checked. If you have a valid license, you see this message:

```
Feature available: PartialReconfiguration
```

If you have no license with the `PartialReconfiguration` feature, contact your local Xilinx sales office for more information. Evaluation licenses are available.

```
place_design
```

```
route_design
```

After both `place_design` and `route_design`, examine the state of the design in the Device view (see Figure 15). One thing to note after `place_design` is the introduction of Partition Pins. These are the physical interface points between static and reconfigurable logic. They are anchor points within an interconnect tile through which each I/O of the Reconfigurable Module must route. They appear as white boxes in the placed design view. For `pblock_shift`, they appear in the top of that Pblock, as the connections to static are just outside the Pblock in that area of the device. For `pblock_count`, they appear outside the user-defined region, as `SNAPPING_MODE` vertically collected more frames to be added to the Reconfigurable Partition.

Figure 15: Partition Pins within Placed Design

2. To find these partition pins in the GUI easily:
 - a. Select the Reconfigurable Module (for example, `inst_shift`) in the Netlist pane.
 - b. Select the **Cell Pins** tab in the Cell Properties pane.
3. Select any pin to highlight it, or use **Ctrl+A** to select all. The Tcl equivalent of the latter is:

```
select_objects [get_pins inst_shift/*]
```

- Use the **Routing Resources** toolbar button  to toggle between abstracted and actual routing information, and to change the visibility of the routing resources themselves. All nets in the design are fully routed at this point.

Figure 16: Close up of First Configuration Routed

Saving the Results

- Save the full design checkpoint and create report files by issuing these commands:

```
write_checkpoint -force Implement/Config_shift_right_count_up_implementation/top_route_design.dcp
report_utilization -file Implement/Config_shift_right_count_up_implementation/top_utilization.rpt
report_timing_summary -file Implement/Config_shift_right_count_up_implementation/top_timing_summary.rpt
```

- [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

```
write_checkpoint -force -cell inst_shift Checkpoint/shift_right_route_design.dcp
write_checkpoint -force -cell inst_count Checkpoint/count_up_route_design.dcp
```

TIP: When running `run_pr.tcl` to process the entire design in batch mode, design checkpoints, log files, and report files are created at each step of the flow.

At this point, you have created a fully implemented partial reconfiguration design from which you can generate full and partial bitstreams. The static portion of this configuration is used for all subsequent configurations. To isolate the static design, remove the current Reconfigurable Modules. Make sure routing resources are enabled, and zoom in to an interconnect tile with partition pins.

7. Clear out Reconfigurable Module logic by issuing the following commands:

```
update_design -cell inst_shift -black_box  
update_design -cell inst_count -black_box
```

Issuing these commands results in many design changes as shown in Figure 17:

- o The number of Fully Routed nets (green) decreased.
- o `inst_shift` and `inst_count` now appear in the Netlist view as empty.

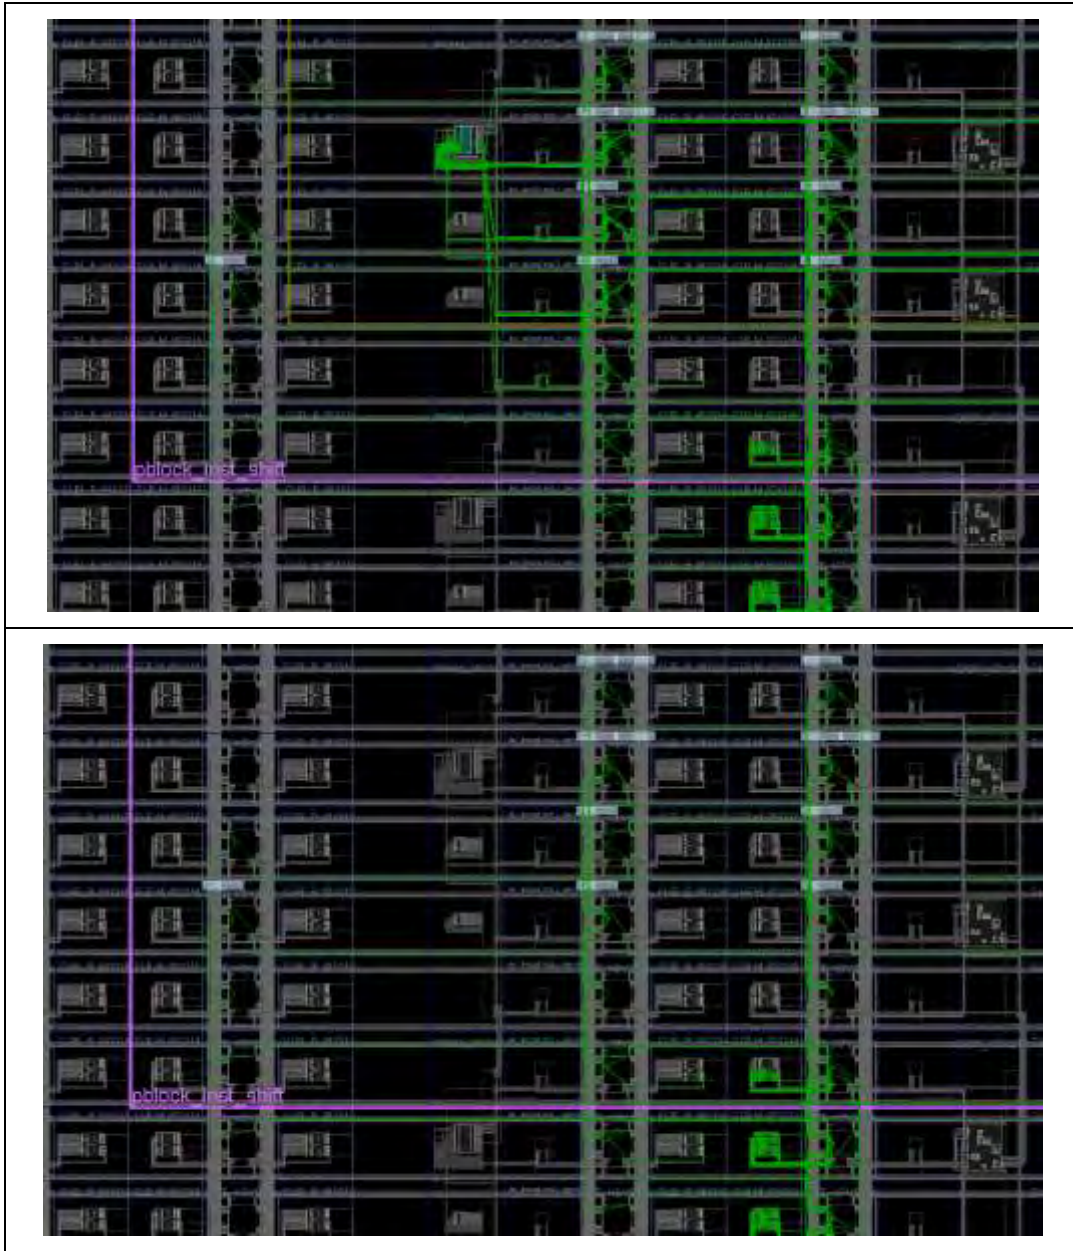

Figure 17: The `inst_shift` module before (top) and after (bottom) `update_design -black_box`

8. Issue the following command to lock down all placement and routing:

```
lock_design -level routing
```

Because no cell was identified in the `lock_design` command, the entire design in memory (currently consisting of the static design with black boxes) is affected. All routed nets now display as locked, as indicated by dashed lines in Figure 18. All placed components changed from blue to orange to show they are also locked.

Figure 18: Close-up of Static-Only Design with Locked Routing

- Issue the following command to write out the remaining static-only checkpoint:

```
write_checkpoint -force Checkpoint/static_route_design.dcp
```

This static-only checkpoint is used for future configurations.

- Close this design before moving on to the next configuration:

```
close_project
```

Step 7: Implementing the Second Configuration

The static design result is now established and locked, and you will use it as context for implementing further Reconfigurable Modules.

Implementing the Design

- Create a new in-memory design by issuing the following command in the Tcl Console:

```
create_project -in_memory -part $part
```

- Load the static design by issuing the following command:

```
add_files ./Checkpoint/static_route_design.dcp
```

- Load the second two synthesis checkpoints for the shift and count functions by issuing these commands:

```
add_file ./Synth/shift_left/shift_synth.dcp

set_property SCOPED_TO_CELLS {inst_shift} [get_files ./Synth/shift_left/shift_synth.dcp]

add_file ./Synth/count_down/count_synth.dcp

set_property SCOPED_TO_CELLS {inst_count} [get_files ./Synth/count_down/count_synth.dcp]
```

4. Link the entire design together using the link_design command:

```
link_design -mode default -reconfig_partitions {inst_shift inst_count} -part $part -top top
```

At this point, a full configuration is loaded. This time, however, the static design is routed and locked, and the reconfigurable logic is still just a netlist. Place and route from here only applies to the RM logic.

5. Optimize, place and route the new RMs in the context of static by issuing these commands:

```
opt_design

place_design

route_design
```

The design is again fully implemented, now with the new Reconfigurable Module variants. The routing is a mix of dashed (locked) and solid (new) routing segments, as shown below.

Figure 19: Second Configuration Routed, Showing Locked and New Routes

Saving the Results

6. Save the full design checkpoint and report files by issuing these commands:

```
write_checkpoint -force Implement/Config_shift_left_count_down_import/top_route_design.dcp
report_utilization -file Implement/Config_shift_left_count_down_import/top_utilization.rpt
report_timing_summary -file Implement/Config_shift_left_count_down_import/top_timing_summary.rpt
```

7. [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

```
write_checkpoint -force -cell inst_shift Checkpoint/shift_left_route_design.dcp
write_checkpoint -force -cell inst_count Checkpoint/count_down_route_design.dcp
```

At this point, you have implemented the static design and all Reconfigurable Module variants. This process would be repeated for designs that have more than two Reconfigurable Modules per Reconfigurable Partition.

Step 8: Examining the Results with Highlighting Scripts

With the routed configuration open in the IDE, run some visualization scripts to highlight tiles and nets. These scripts identify the resources allocated for partial reconfiguration, and are automatically generated. For UltraScale and UltraScale+ devices, there are different scripts to show the range for placement versus routing for a given Pblock.

1. In the Tcl Console, issue the following commands from the <Extract_Dir> directory:

```
source hd_visual/pblock_inst_shift_Routing_AllTiles.tcl
highlight_objects -color green [get_selected_objects]
```
2. Click somewhere in the Device view to deselect the frames (or enter `unselect_objects`), then issue the following commands:

```
source hd_visual/pblock_inst_shift_Placement_AllTiles.tcl
source hd_visual/pblock_inst_count_Placement_AllTiles.tcl
highlight_objects -color blue [get_selected_objects]
```

The partition frames appear highlighted in the Device view, as shown in Figure 20.

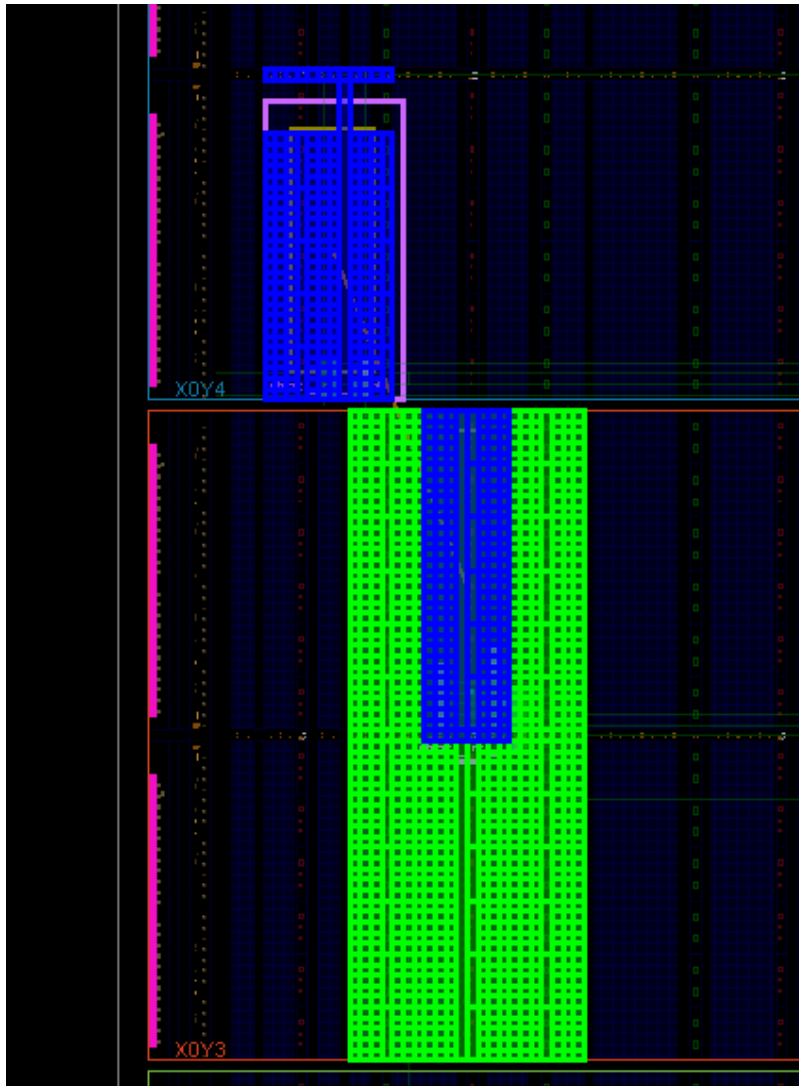

Figure 20: Reconfigurable Partition Frames Highlighted

These highlighted tiles represent the configuration frames used for placement (blue) and routing (green) for each RM. The green tiles are sent to bitstream generation to create the partial bitstream (for `inst_shift`). The `SNAPPING_MODE` feature adjusted three of four edges of `pblock_shift` to account for alignment to programmable unit boundaries. This snapping behavior explains why it appears that static logic may appear to have been placed inside Reconfigurable Partitions, as seen in Figure 17, Figure 18, and Figure 19. In actuality, the effective boundary is one CLB row higher than the user-defined Pblock boundary indicates, so this static logic is placed correctly. This effective boundary can also be seen in the shading of the Pblock during creation, as shown in Figure 12 and Figure 13.

Also note that RCLK rows matching the width of the Pblocks are included. Global clocks driving logic in these Reconfigurable Partitions are connected to the spines running through these rows and are enabled or disabled during partial reconfiguration.

The other “tile” scripts are variations on these. If you had not created Pblocks that vertically aligned to the clock region boundaries, the FrameTiles script would highlight the explicit Pblock tiles, while the AllTiles script extends those tiles to the full reconfigurable frame height. Note that these leave gaps where unselected frame types (for example: global clocks) exist.

The GlitchTiles script is a subset of frame sites, avoiding dedicated silicon resources; the other scripts are more informative than this one.

3. Close the current design:

```
close_project
```

Step 9: Generating the Bitstreams

Verifying the Configurations

RECOMMENDED: Before generating bitstreams, verify all configurations to ensure that the static portion of each configuration match identically, so the resulting bitstreams are safe to use in silicon. The PR Verify feature examines the complete static design up to and including the partition pins, confirming that they are identical. Placement and routing within the Reconfigurable Modules is not checked, as different module results are expected here.

1. Run the `pr_verify` command from the Tcl Console:

```
pr_verify Implement/Config_shift_right_count_up_implement/top_route_design.dcp
Implement/Config_shift_left_count_down_import/top_route_design.dcp
```

If successful, this command returns the following message.

```
INFO: [Vivado 12-3253] PR_VERIFY: check points
Implement/Config_shift_right_count_up/top_route_design.dcp and
Implement/Config_shift_left_count_down/top_route_design.dcp are compatible
```

By default, only the first mismatch (if any) is reported. To see all mismatches, use the `-full_check` option.

2. Close the project:

```
close_project
```

Generating Bitstreams

Now that the configurations have been verified, you can generate bitstreams and use them to target your selected demonstration board.

Note: The first configuration implements `shift_right` and `count_up`. The second configuration implements `shift_left` and `count_down`.

3. First, read the first configuration into memory:

```
open_checkpoint Implement/Config_shift_right_count_up_implement/top_route_design.dcp
```

4. Generate full and partial bitstreams for this design. Be sure to keep the bit files in a unique directory related to the full design checkpoint from which they were created.

```
write_bitstream -force -file Bitstreams/Config_RightUp.bit
```

```
close_project
```

Notice that five (or three, if you are using an UltraScale+ device) bitstreams have been created:

- o `Config_RightUp.bit`
This is the power-up, full design bitstream. The four shift LEDs on the right will shift right and the four count LEDs on the left will count up.
- o `Config_RightUp_pblock_inst_shift_partial.bit`
This is the partial bit file for the `shift_right` module that causes the shift LEDs to shift right.
- o `Config_RightUp_pblock_inst_count_partial.bit`
This is the partial bit file for the `count_up` module that causes the count LEDs to count up.
- o `Config_RightUp_pblock_inst_shift_partial_clear.bit`
This is the clearing bit file for the `shift_right` module for UltraScale devices only. It safely clears a right shift to allow the shift module to be reconfigured.
- o `Config_RightUp_pblock_inst_count_partial_clear.bit`
This is the clearing bit file for the `count_up` module for UltraScale devices only. It safely clears an up count to allow the count module to be reconfigured.

IMPORTANT: When generated by a single call to `write_bitstream`, the names of the bit files currently do not reflect the name of the Reconfigurable Module variant to clarify which image is loaded. The current solution uses the base name given by the `-file` option and appends the Pblock name of the reconfigurable cell. It is critical to provide enough description in the base name to be able to identify the reconfigurable bit files clearly. All partial bit files have the `_partial` postfix, and all clearing bit files have the `_partial_clear` postfix.

Using `run_pr.tcl` to process the entire design through bitstream generation, uses a different technique for generating the bitstreams. Opening a routed design checkpoint issues multiple calls to `write_bitstream`, which gives you more control over naming bitstreams and allows for different options (such a bitstream compression) to be applied to full versus partial bitstreams. For example, the names configured in the `run_pr.tcl` script are:

- o `Config_shift_right_count_up_implement_full.bit`
This is the power-up, full design bitstream.

- o `pblock_shift_shift_right_partial.bit`
This is the partial bit file for the `shift_right` module.
- o `pblock_count_count_up_partial.bit`
This is the partial bit file for the `count_up` module.
- o `pblock_shift_shift_right_partial_clear.bit`
This is the clearing bit file for the `shift_right` module for UltraScale devices only.
- o `pblock_count_count_up_partial_clear.bit`
This is the clearing bit file for the `count_up` module for UltraScale devices only.

5. Generate full and partial bitstreams for the second configuration, again keeping the resulting bit files in the appropriate folder.

```
open_checkpoint Implement/Config_shift_left_count_down_import/top_route_design.dcp
```

```
write_bitstream -force -file Bitstreams/Config_LeftDown.bit
```

```
close_project
```

Similarly, five (or three) bitstreams are created, this time with a different base name.

6. Generate a full bitstream with grey boxes, plus blanking bitstreams for the Reconfigurable Modules. Blanking bitstreams can be used to “erase” an existing configuration to reduce power consumption.

Note: Grey box blanking bitstreams are not the same as clearing bitstreams. Clearing bitstreams are required to prepare the global signal mask for the next partial bitstream, ensuring the GSR event occurs properly.

```
open_checkpoint Checkpoint/static_route_design.dcp
```

```
update_design -cell inst_count -buffer_ports
```

```
update_design -cell inst_shift -buffer_ports
```

```
place_design
```

```
route_design
```

```
write_checkpoint -force Checkpoint/config_grey_box.dcp
```

```
write_bitstream -force -file Bitstreams/config_grey_box.bit
```

```
close_project
```

The base configuration bitstream has no logic for either reconfigurable partition. The `update_design` commands here insert constant drivers (ground) for all outputs of the Reconfigurable Partitions, so these outputs do not float. The term *grey box* indicates that the modules are not completely empty with these LUTs inserted, as opposed to black boxes, which would have dangling nets in and out of this region. The `place_design` and `route_design` commands ensure they are completely implemented. As valid Reconfigurable Modules, note that these instances also have clearing bitstreams for UltraScale devices only.

Step 10: Partially Reconfiguring the FPGA

The `count_shift_led` design targets one of four demonstration boards. The current design supports the KCU105, VCU108, KCU116, and VCU118 boards, revisions Rev 1.0 and newer.

Configuring the Device with a Full Image

1. Connect the board to your computer using the Platform Cable USB and power on the board.
2. From the main Vivado IDE, select **Flow > Open Hardware Manager**.
3. Select **Open target** on the green banner. Follow the steps in the wizard to establish communication with the board.
4. Select **Program device** on the green banner and pick the target device, e.g. **xcku040_0**.
5. Navigate to the Bitstreams folder to select `Config_RightUp.bit`, then click **OK** to program the device.

You should now see the bank of GPIO LEDs performing two tasks. Four LEDs are performing a counting-up function (MSB is on the left), and the other four are shifting to the right. Note the amount of time it took to configure the full device.

Partially Reconfiguring the Device

At this point, you can partially reconfigure the active device with any of the partial bitstreams that you have created, starting first with the appropriate clearing bitstream.

6. UltraScale targets only: Select **Program device** on the green banner again. Navigate to the Bitstreams folder to select `Config_RightUp_pblock_inst_shift_partial_clear.bit`, then click **OK** to program the device.

The shift portion of the LEDs stopped, but the counter kept counting up, unaffected by the reconfiguration. Note the much shorter configuration time, as well as the fact that the DONE LED turned off.

7. UltraScale targets only: Select **Program device** on the green banner again. Navigate to the Bitstreams folder to select `Config_LeftDown_pblock_inst_shift_partial.bit`, then click **OK** to program the device.

The shift portion of the LEDs restarted in the opposite direction, and the DONE LED is back on.

8. Select **Program device** on the green banner again. Navigate to the `Bitstreams` folder to select `Config_RightUp_pblock_inst_count_partial_clear.bit`, then click **OK** to program the device.

The count portion of the LEDs stopped, but the shifter kept shifting, unaffected by the reconfiguration.

9. Select **Program device** on the green banner again. Navigate to the `Bitstreams` folder to select `Config_LeftDown_pblock_inst_count_partial.bit`, then click **OK** to program the device.

The counter is now counting down, and the shifting LEDs were unaffected by the reconfiguration. This process can be repeated with the `Config_RightUp` partial bit files to return to the original configuration, or with the blanking partial bit files to stop activity on the LEDs (they will stay on). Keep track of the currently loaded module for each partition to ensure the correct clearing bitstream is loaded before the next partial bitstream.

Conclusion

This concludes Lab 2. In this lab, you:

- Synthesized a design bottom-up to prepare for partial reconfiguration implementation
- Created a valid floorplan for a partial reconfiguration design
- Created two configurations with common static results
- Implemented these two configurations, saving the static design to be used in each
- Created checkpoints for static and reconfigurable modules for later reuse
- Examined framesets and verified the two configurations
- Created full, partial, and clearing bitstreams
- Configured and partially reconfigured an FPGA

Lab 3: Partial Reconfiguration Project Flow

Overview

In this lab, you will create a new project and set up all the sources and runs defining the structure of a PR design. The design used in this lab is based on the simple design in labs 1 and 2, but modified so it has two instances of the shift module instead of one shift and one count. This shows the implications of Partition Definitions in the project flow.

This lab currently targets the following Xilinx® development platforms:

- KC705 (Kintex™-7)
- VC707 (Virtex™-7)
- VC709 (Virtex-7)
- KCU105 (Kintex UltraScale™)
- VCU108 (Virtex UltraScale)
- KCU116 (Kintex UltraScale+™)
- VCU118 (Virtex UltraScale+)

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see Tutorial Design Description.
2. Navigate to `\pr_project` in the extracted files. The `pr_project` data directory is referred to in this lab as the `<Extract_Dir>`.

Step 2: Loading Initial Design Sources

The first unique step in any PR design flow (project based or otherwise) is to define the parts of the design that will be marked reconfigurable. This is done via context menus in the **Hierarchical Source View** in project mode. These steps will walk through initial project creation through definition of partitions in a simple design.

1. Extract the design from the archive. The `pr_project` data directory is referred to in this tutorial as the `<Extract_Dir>`.
2. Open the Vivado IDE and select **Create Project**, then click **Next**.

3. Select the `<Extract_Dir>` as the **Project location**. Leave the **Project name** as `project_1`, and leave the **Create project subdirectory** option checked. Click **Next**.
4. Select **RTL Project** and ensure the **Do not specify sources** checkbox is unchecked, then click **Next**.
5. Click the **Add Directories** button and select these Sources directories to be added to the design:
 - o `<Extract_Dir>\Sources\hdl\top`
 - o `<Extract_Dir>\Sources\hdl\shift_right`
6. Click **Next** to get to the Add Constraints window, then select these files:
 - o `<Extract_Dir>\Sources\xdc\top_io_<board>.xdc`
 - o `<Extract_Dir>\Sources\xdc\pblocks_<board>.xdc`

Note that these constraint files are full design constraints, scoped to the top level design. If you would like to perform your own floorplanning, only select the `top_io` xdc, omitting the `pblocks` xdc. Stop the flow after synthesis to create your own floorplan.

7. Click **Next** to choose the part. In the Part selector, click on **Boards** and choose the target board matching the constraint file(s) you have selected. Then click **Next** and then **Finish** to complete project creation. The Sources window shows a standard hierarchical view of the design.

Figure 21: Sources View After Project Creation

At this point, a standard project is open. Nothing specific to Partial Reconfiguration has been done.

8. Select **Tools > Enable Partial Reconfiguration**

This prepares the project for the PR design flow. Once this is set it cannot be undone, so archive your project before selecting this option.

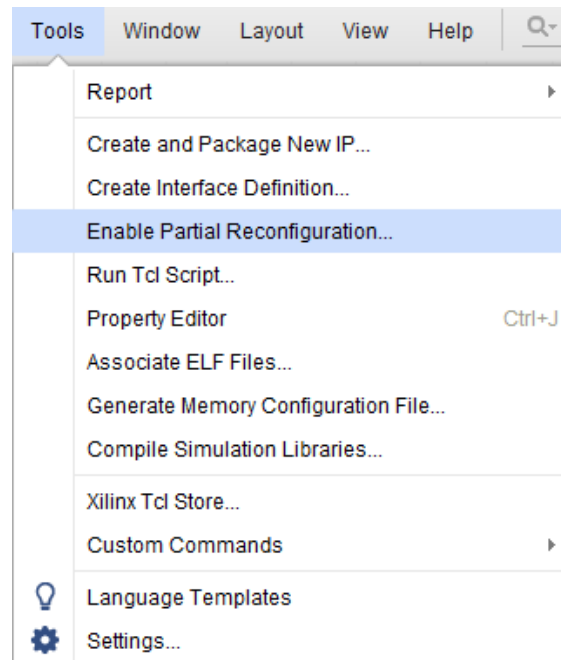

Figure 22: Enabling Partial Reconfiguration

In the ensuing dialog box, click **Convert** to turn this project into a PR project.

9. Right-click on one of the "shift" instances and select the **Create Partition Definition...** option.

This action will define *both* shift instances as Reconfigurable Partitions in the design. Since each instance has come from the same RTL source, they are logically identical. Out-of-context synthesis will be run to keep this module separated from top, and the one post-synthesis checkpoint will be used for both shift instances.

TIP: *If there are multiple instantiations of the same module within a design, but not all need to be reconfigurable, then the modules must be manually modified to become unique. Then you can independently tag desired instances as Reconfigurable Partitions.*

10. In the dialog box that appears, give names to both the Partition Definition and the Reconfigurable Module. The Partition Definition is the general reference for the workspace into which all Reconfigurable Modules will be inserted, so give it an appropriate name, such as `shifter`. The Reconfigurable Module refers to this specific RTL instance, so give it a name that references its functionality, such as `shift_right`, then click **OK**.

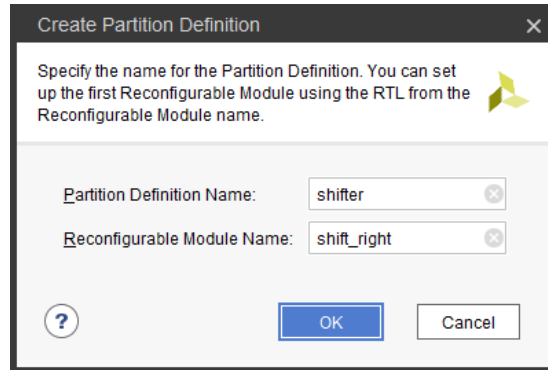

Figure 23: Creating the `shifter` Partition Definition

The **Sources** view has now changed slightly, with both shift instances now shown with a yellow diamond, indicating they are Partitions. You will also see a **Partition Definitions** tab in this window, showing the list and contents of all Partition Definitions (just one at this point) in the design. In addition, an out-of-context module run has been created for synthesizing the `shift_right` module.

Figure 24: Sources view after shift partition has been defined

At this point, more Reconfigurable Module sources may be added. This is done via the Partial Reconfiguration Wizard.

IMPORTANT: After Partitions have been defined, all additional RMs must be added via the Partial Reconfiguration Wizard, and any management of RM sources, configurations, and runs must also be done via this wizard.

Step 3: Completing the Design with the Partial Reconfiguration Wizard

1. Launch the **Partial Reconfiguration Wizard** by selecting this option under the Tools menu or from the Flow Navigator.
2. Click **Next** to get to the **Edit Reconfigurable Modules** page. Here you can see the `shift_right` RM already exists, and there are add, remove and edit buttons on the left hand side of the window, above the RMs. Click on the blue + icon to add a new RM.
3. Click the Add Directories button to select the `shift_left` folder:

```
<Extract_Dir>\Sources\hdl\shift_left
```

Or use the Add Files button to select the `shift_left.v` file residing in this directory. If module-level constraints were needed, they would be added here. Note that they would need to be scoped to the level of hierarchy for this Partition.

Fill in the Reconfigurable Module field to be `shift_left`. Set the Partition Definition to be `shifter`, leave **Top Module** field empty and the **Sources are already synthesized** check box unchecked. Click **OK** to create the new module.

Two Reconfigurable Modules are now available for the `shifter` Reconfigurable Partition.

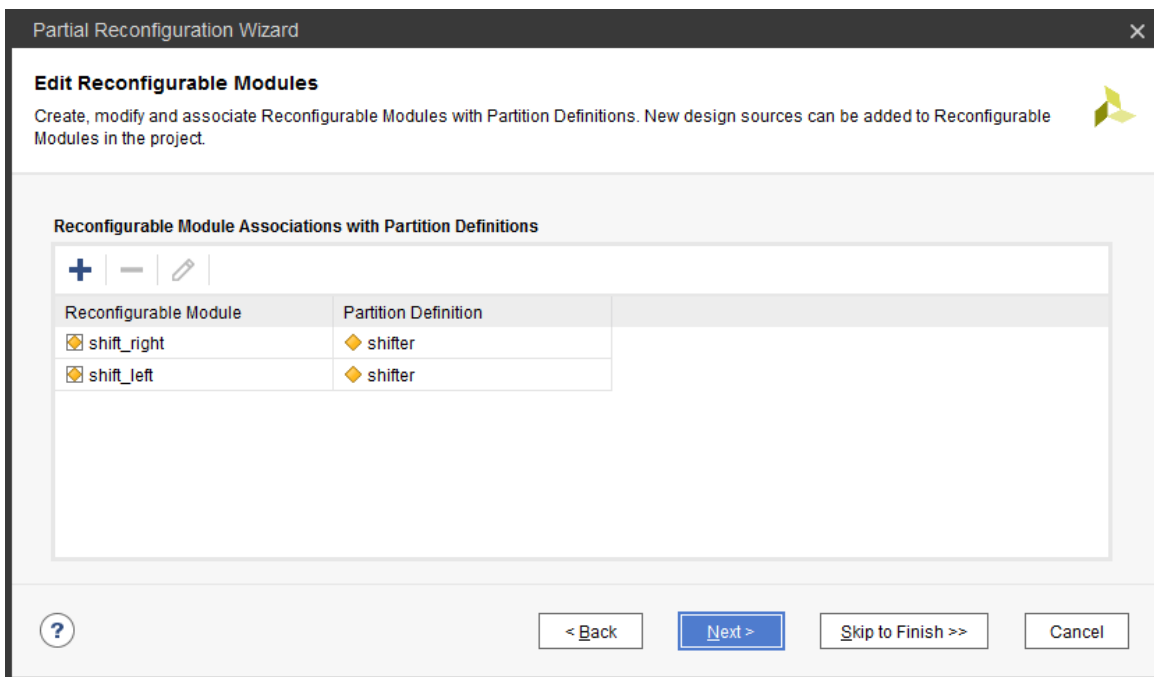

Figure 25: Partial Reconfiguration Wizard with two Reconfigurable Modules defined

On the next page, **Configurations** are defined. Configurations are full design images consisting of the static design and one RM per RP. You can either create any desired set of configurations, or simply let the wizard select them for you.

- Let the Wizard create the configurations by selecting the **automatically create configurations** link.

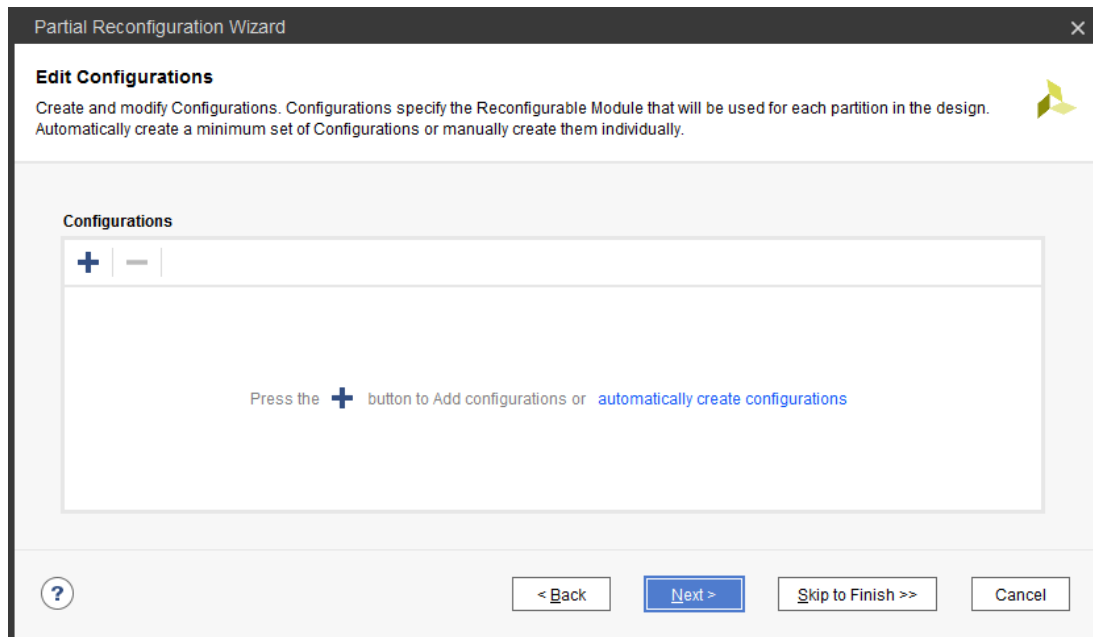

Figure 26: Partial Reconfiguration Wizard Configurations page

After selecting this option, the minimum set of two configurations has been created. Each shift instance has been given **shift_right** in the first configuration and **shift_left** in the second configuration. Note that the **Configuration Name** is editable – in the example below, the names have been updated to **config_right** and **config_left** to reflect the Reconfigurable Modules contained within each one.

Figure 27: Auto-Generated minimum set of Configurations

Additional configurations can be created by using these two Reconfigurable Modules, but two is all you need to create all the partial bitstreams necessary for this version of the design, as the maximum number of RMs for any RP is two.

5. Click **Next** to get to the **Edit Configuration Runs** page.

As with configurations themselves, the runs used to implement each configuration can be automatically or manually created. A parent-child relationship will define how the runs interact – the parent run implements the static design and all RMs within that configuration, then child runs reuse the locked static design while implementing the RMs within that configuration in that established context.

6. Click on the **automatically create configuration run** link to populate the Configuration Runs page with the minimum set of runs.

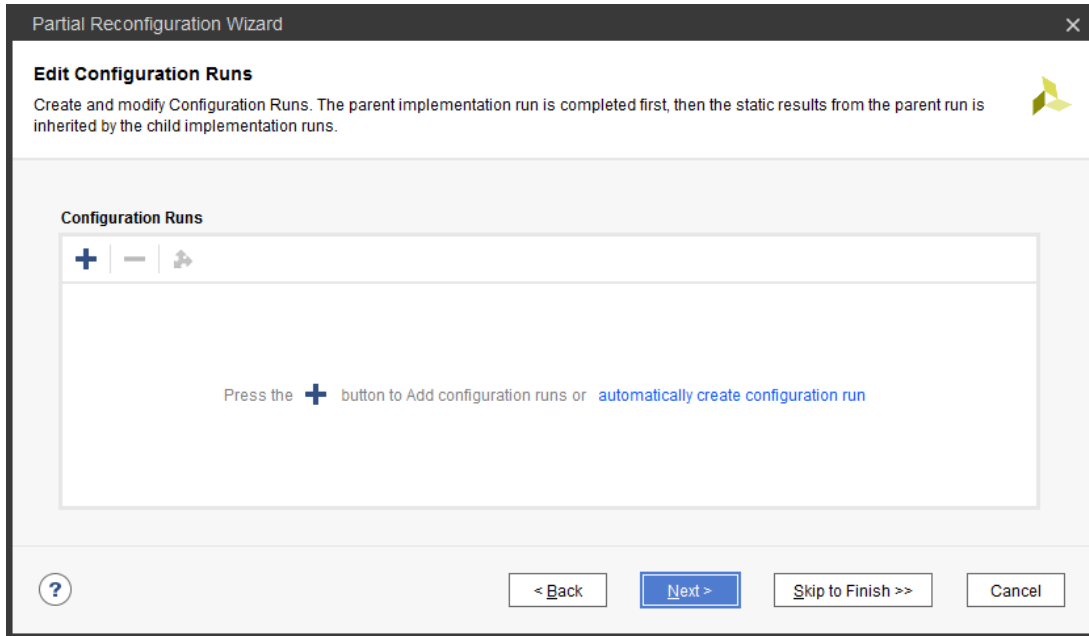

Figure 28: Partial Reconfiguration Wizard

This creates two runs, consisting of one parent configuration (**config_right**) and one child configuration (**config_left**). Any number of independent or related runs can be created within this wizard, with options for using different strategies or constraint sets for any of them. For now, leave this set to the two runs set here. Note that the names of the runs are not editable.

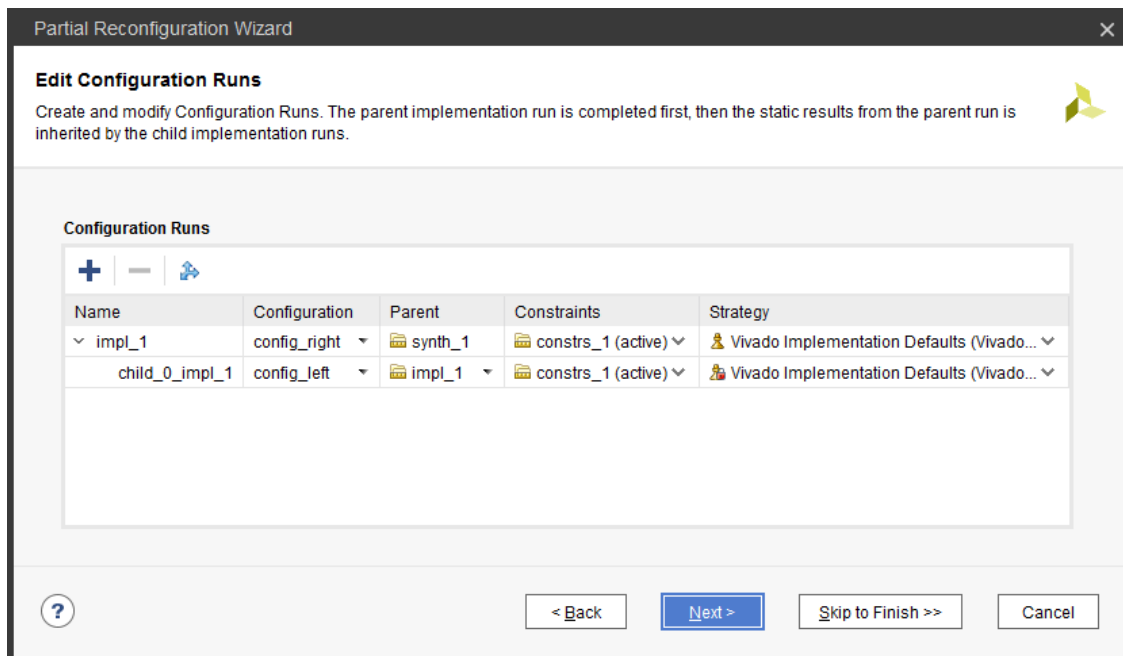

Figure 29: Auto-generated Minimum set of Configuration Runs

- Click **Next** to see the Summary page then Finish to complete the design setup and exit the Wizard.

IMPORTANT: Nothing is created or modified until you click Finish to exit the Partial Reconfiguration Wizard. All actions are queued until this last click, so it is possible to step forward and back as needed without implementing changes until you are ready.

Back in the Vivado IDE, you will see that the **Design Runs** window has been updated. A second out-of-context synthesis run has been added for the **shift_left** RM, and a child implementation run (**child_0_impl_1**) has been created under the parent (**impl_1**). You are now ready to process the design.

Name	Configuration	Constraints	Status	WNS
synth_1 (active)		constrs_1	Not started	
impl_1 (active)	config_right	constrs_1	Not started	
child_0_impl_1	config_left	constrs_1	Not started	
Out-of-Context Module Runs				
shift_right_synth_1		shift_right	Not started	
shift_left_synth_1		shift_left	Not started	

Figure 30: Design Runs window showing all synthesis and implementation ready to launch

Step 4: Synthesizing and Implementing the Current Design

With the design from above open in the Vivado IDE, take a look at the **Design Runs** window. The top-level design synthesis run (synth_1) and the parent implementation run (impl_1) are marked "active." The Flow Navigator actions apply to these active runs and their child runs, so clicking on **Run Synthesis** or **Run Implementation** pulls the design through only these runs, as well as the OOC synthesis runs needed to complete them. You can select a specific parent or child implementation run, right-click and select **Launch Runs** to pull through the entire flow for that ultimate target.

- In the Flow Navigator, click **Run Synthesis**. When synthesis completes, select **Open Synthesized Design**.

This action will synthesize all OOC modules, followed by synthesis of the top level design. This is no different than any design with OOC modules (IP or otherwise).

In the post-synthesis design that opens, note that two Pblocks have already been defined. These were supplied in `pblocks_<board>.xdc` and map to the two shift instances in top. If no Pblocks had existed with the design sources, they could be created at this step in the

flow. This can be done by right-clicking on an inst_shift instance in the design hierarchy to select **Floorplanning > Draw Pblock**. Each instance will require its own unique Pblock.

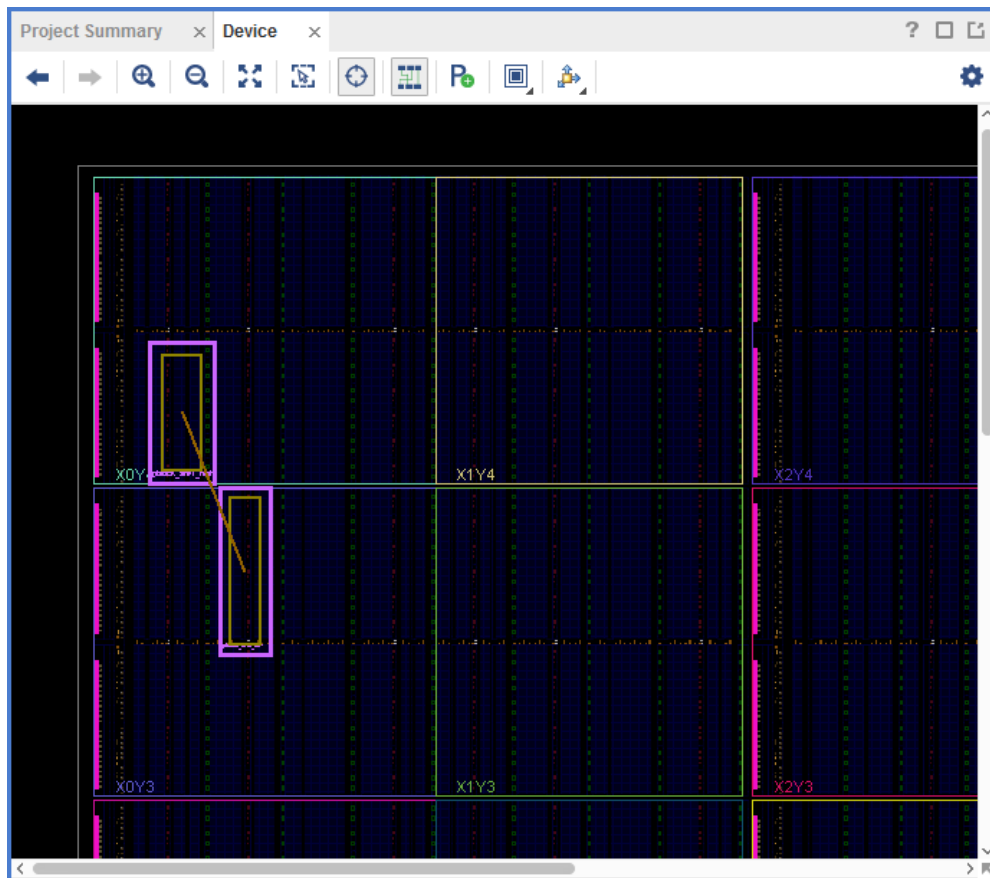

Figure 31: Floorplan with two Reconfigurable Partitions (KC105 shown)

2. Select one of the two Pblocks in the floorplan and note its properties. The last two properties listed are RESET_AFTER_RECONFIG (7 series only) and SNAPPING_MODE, two properties specific to Partial Reconfiguration. Note that both of these options have been enabled in the Pblocks xdc.
3. Run PR-specific design rule checks by selecting **Reports > Report DRC**. To save time, you can deselect all checkboxes other than the one for Partial Reconfiguration.

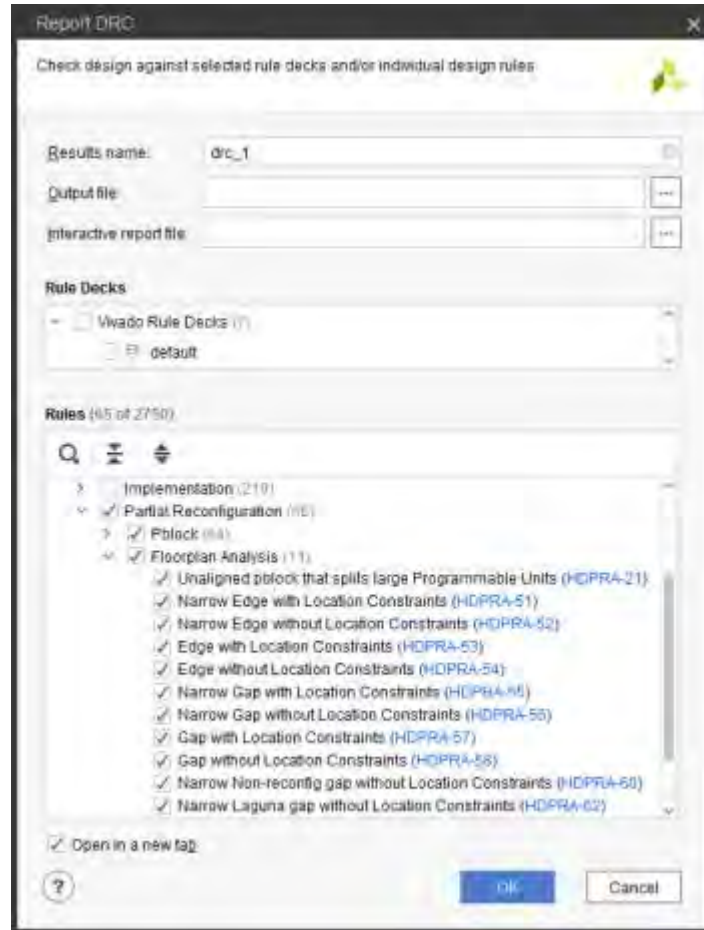

Figure 32: Checking Partial Reconfiguration DRCs

DRC checks will report no errors with the supplied sources and constraints. Advisory messages may be given for certain devices with suggestions on how to improve the quality of the given Pblocks. These can be ignored for this simple design.

If you have created your own floorplan and DRCs have been reported, fix the issues before moving on. Note that both modules will require BRAM resources, and remember that SNAPPING_MODE will resolve any errors related to horizontal or vertical alignment.

TIP: Run Partial Reconfiguration Design Rule Checks early and often.

4. In the Flow Navigator, select **Run Implementation** to run place and route on all configurations.

This action runs implementation first for impl_1 and then for child_0_impl_1. Behind the scenes, Vivado takes care of all the details. In addition to running place and route for the two runs with all the PR requirements in place, it does a few more tasks specific to PR. After impl_1 completes, Vivado automatically:

- Writes module-level (OOC) checkpoints for each routed shift_right RM.
- Carves out the logic in each RP to create a static-only design image for the top. This is done by calling `update_design -black_box` for each instance.
- Locks all placement and routing for the static-only portion of the design. This is done by calling `lock_design -level routing`.
- Saves the locked static parent image to be reused for all child runs.

In addition, when the child run completes, module-level checkpoints are created for the routed shift_left RMs. A locked static design image would be identical to the parent, so this step is not necessary.

If only specific configuration runs are desired, these can be individually selected within the Design Runs window. Note that a parent run must be completed successfully before a child run can be launched, as the child run starts with the locked static design from the parent.

5. When Implementation completes, click **Cancel** in the resulting pop-up dialog.

CAUTION! Even though the design has been processed through to the child implementation run, selecting **Open Implemented Design** opens the parent run by default. Use the pulldown selection to choose the desired implementation run..

Name	Configuration	Constraints	Status	WNS	TNS	WHS	THS
✓ synth_1 (active)		constrs_1	synth_design Complete!				
<ul style="list-style-type: none"> ✓ impl_1 (active) ✓ child_0_impl_1 	<ul style="list-style-type: none"> config_right config_left 	<ul style="list-style-type: none"> constrs_1 constrs_1 	<ul style="list-style-type: none"> route_design Complete! route_design Complete! 	<ul style="list-style-type: none"> 8.254 8.254 	<ul style="list-style-type: none"> 0.000 0.000 	<ul style="list-style-type: none"> 0.079 0.079 	<ul style="list-style-type: none"> 0.000 0.000
Out-of-Context Module Runs							
✓ shift_right_synth_1		shift_right	synth_design Complete!				
✓ shift_left_synth_1		shift_left	synth_design Complete!				

Figure 33: All Configurations Routed

At this point, there are two steps remaining. The first is running PR Verify to compare the two configurations to ensure consistency of the static part of the design images. This step is highly recommended and will occur automatically within the Vivado project. The second step is to generate the bitstreams themselves.

6. In the Flow Navigator, click **Generate Bitstream**. This action launches bitstream generation on the active parent run, and launches PR Verify and then bitstream generation on all implemented child runs.

For each configuration run, both full and partial bitstreams are generated by default.

The entire Partial Reconfiguration flow can now be run in a project environment. All steps, from module-level synthesis to bitstream generation can be done without leaving the GUI.

Step 5: Adding an Additional Reconfigurable Module and Corresponding Configuration

1. With the design open in the Vivado IDE, open the **Partial Reconfiguration Wizard**.
2. On the **Edit Reconfigurable Modules** page, click the + button to add a new RM.
3. Select the `shift_right_slow.v` file in `<Extract_Dir>\Sources\hdl\shift_right_slow` then click **OK**.
4. Enter `shift_right_slow` for the Reconfigurable Module name and then click **OK** and **Next**.

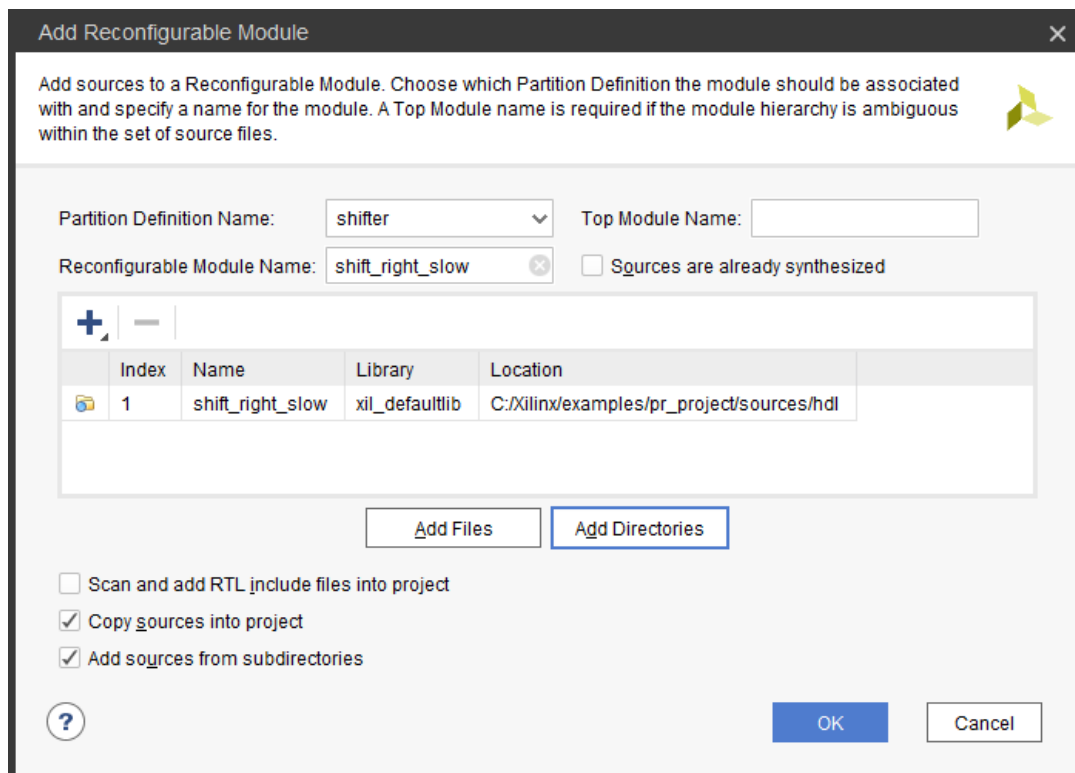

Figure 34: Adding a new RM `shift_right_slow`

Note that on the Edit Configurations page, there is no longer an option to automatically create configurations, as you already have two existing ones. You can re-enable this option by removing all existing configurations, but this will recreate all configurations and remove all existing results.

5. Create a new configuration by clicking the + button, entering the name **config_right_slow**, then hitting ENTER. Select **shift_right_slow** for each Reconfigurable Partition instance.

Figure 35: Creating the config_right_slow Configuration

6. Click **Next** to advance to the Configuration Runs. Use the + button to create a new configuration with these properties:
 - o Run: child_1_impl_1 - this simply matches the existing convention
 - o Parent: impl_1 - this makes this configuration a child run of the existing parent run
 - o Configuration: config_right_slow - this is the one with the new RMs that was just defined
7. Click **OK** to add the new Configuration Run.

Figure 36: Creating a new Configuration Run

This new configuration, as a child of the existing impl_1, will reuse the static design implementation results, just like config_left did. Three runs now exist, with two as children of the initial parent. The green check marks indicate that two of the runs are currently complete.

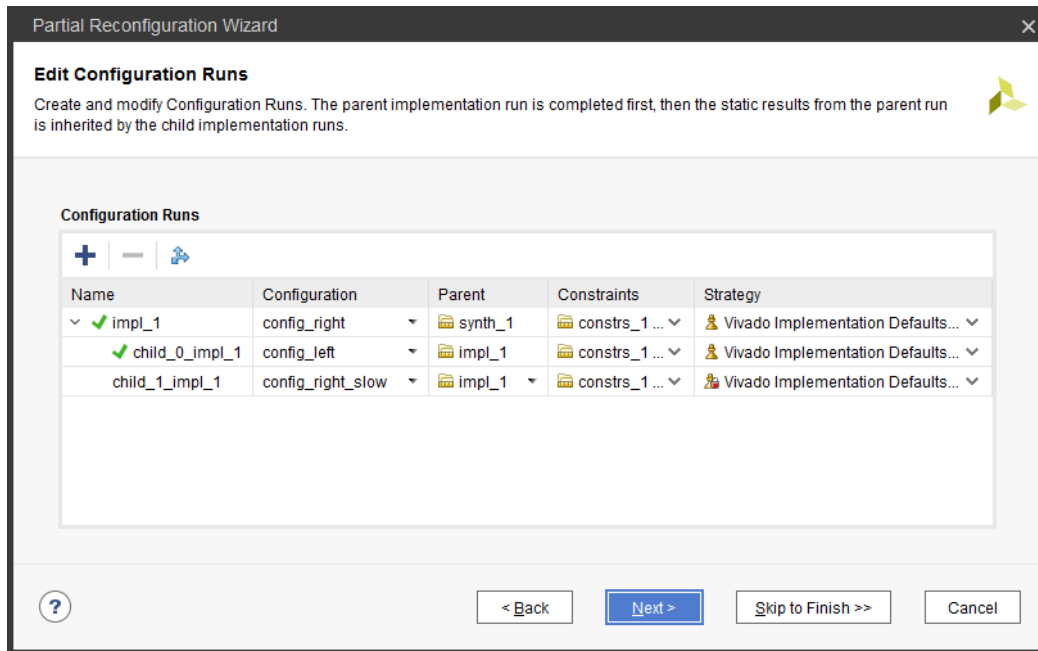

Figure 37: The config_right_slow configuration added as a new child run

- Click **Next**, then **Finish** to build this new configuration run.

Name	Configuration	Constraints	Status	WNS	TNS	WHS	THS
✓ synth_1 (active)		constrs_1	synth_design Complete!				
✓ impl_1 (active)	config_right	constrs_1	route_design Complete!	8.254	0.000	0.079	0.000
✓ child_0_impl_1	config_left	constrs_1	route_design Complete!	8.254	0.000	0.079	0.000
▶ child_1_impl_1	config_right_slow	constrs_1	Not started				
Out-of-Context Module Runs							
✓ shift_right_synth_1		shift_right	synth_design Complete!				
✓ shift_left_synth_1		shift_left	synth_design Complete!				
▶ shift_right_slow_synth_1		shift_right_slow	Not started				

Figure 38: New OOC synthesis run and Configuration run added

- Select this new child implementation run, right-click and select **Launch Runs**. This will run OOC synthesis on the shift_right_slow module, then will implement this module within the context of the locked static design.

Step 6: Creating and Implementing a Greybox Module

For some designs, it may not be clear which Reconfigurable Module is the most difficult to implement. Or perhaps there are no Reconfigurable Modules available. A greybox implementation can be used to implement just the static design without real RM netlists available.

A greybox is a module that starts off as a blackbox, but then has LUTs automatically inserted for all ports. Output ports are driven to a logic 0 (by default, 1 is selectable via property) so they do not float. This module allows the design to be processed even if no RMs are available. Training scripts are available to create timing budgets for this greybox image, optimizing the implementation results of the static design. A configuration with greybox RMs can be the parent run, but this is only recommended when no other RMs exist and/or when budgeting constraints are used to optimize the RP interface placement.

1. Open the Partial Reconfiguration Wizard and move to the Configurations page – no new Reconfigurable Modules need to be defined in this case. Create a new configuration a name of **config_greybox** and enter `<greybox>` for each Reconfigurable Partition instance.

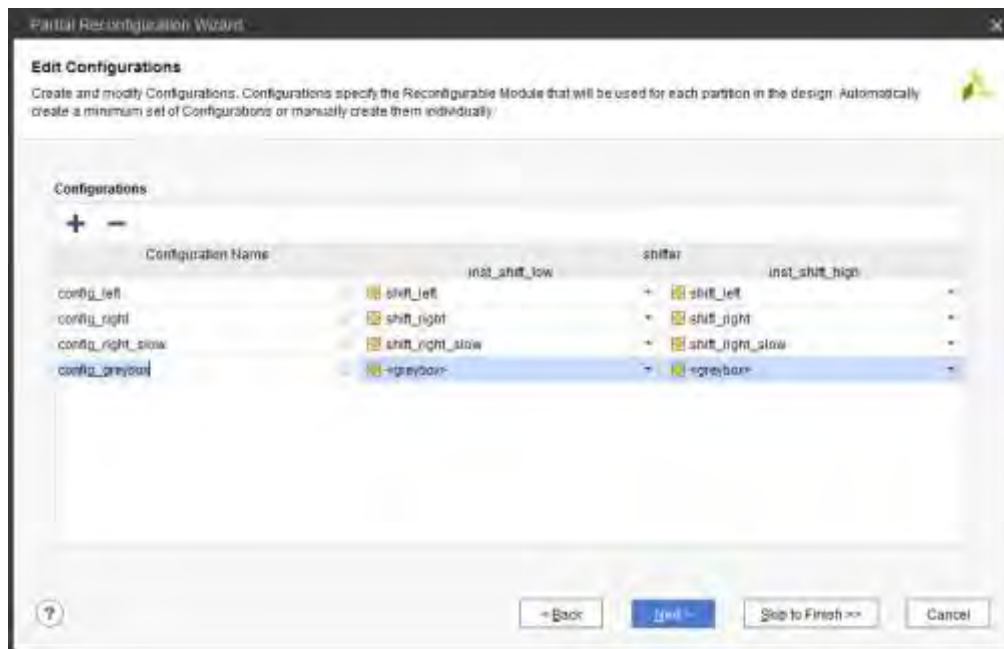

Figure 39: Adding the new config_greybox Configuration

2. Click **Next** to get to the Configuration Runs page, then create another new configuration run, this time for the greybox configuration.
 - o Parent: synth_1 – this makes this configuration a new parent, starting from the synthesized top level design
 - o Configuration: config_greybox – the RMs consist only of LUT tie-offs
 - o Run: impl_greybox

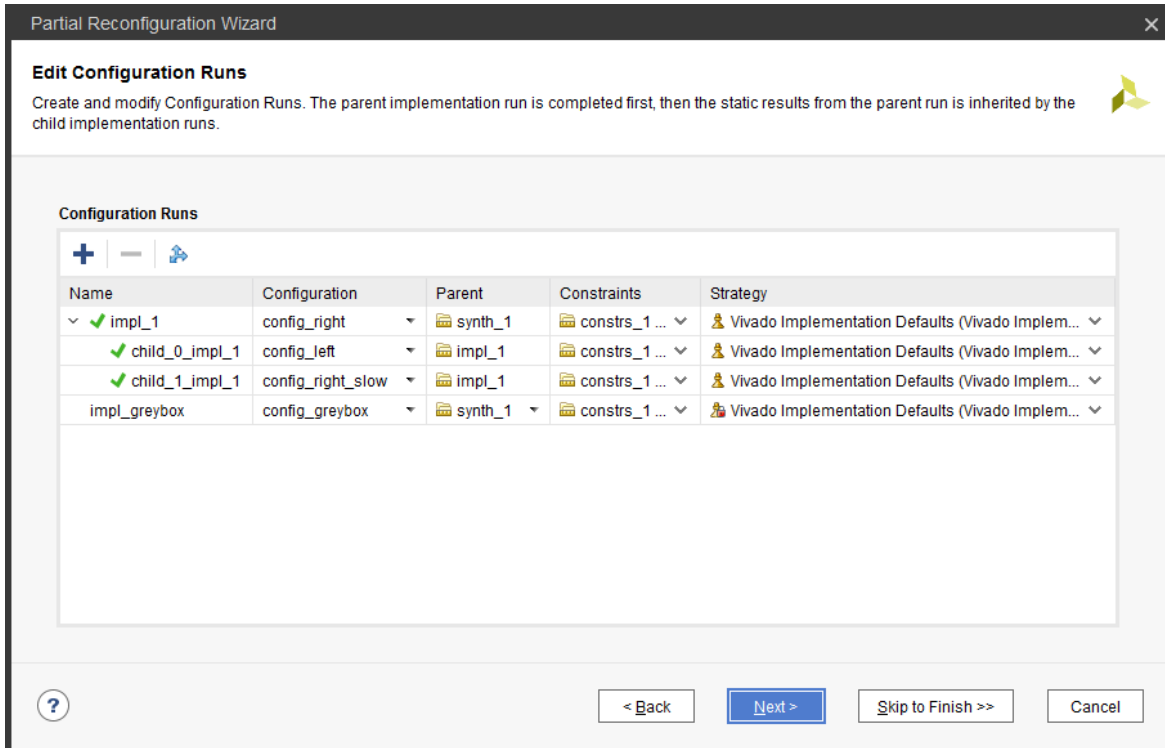

Figure 40: Creating an independent greybox Configuration Run

At this point, four configuration runs have been defined. Two are parents, and two are children of the first parent.

- Click **Next** then **Finish** to create this new run.

Now there are four implementation runs and three out-of-context runs shown in the Design Runs window. Note that the greybox module does not require synthesis – it is an embedded feature in the PR solution.

Name	Configuration	Constraints	Status	WNS	TNS	WHS	THS
synth_1 (active)		constrs_1	synth_design Complete!				
impl_1 (active)	config_right	constrs_1	route_design Complete!	8.254	0.000	0.079	0.000
child_0_impl_1	config_left	constrs_1	route_design Complete!	8.254	0.000	0.079	0.000
child_1_impl_1	config_right_slow	constrs_1	route_design Complete!	8.254	0.000	0.079	0.000
impl_greybox	config_greybox	constrs_1	Not started				
Out-of-Context Module Runs							
shift_right_synth_1		shift_right	synth_design Complete!				
shift_left_synth_1		shift_left	synth_design Complete!				
shift_right_slow_synth_1		shift_right_slow	synth_design Complete!				

Figure 41: Greybox Implementation Ready to Run

At this point the greybox configuration can be implemented.

4. Select the **impl_greybox** design run, right-click and select **Launch Runs**. The Flow Navigator will not launch this run as it is not the active parent.

IMPORTANT: Because impl_1 and impl_greybox are both parents, their static design results will be different, and their resulting bitstreams will NOT be compatible in hardware. Only bitstreams derived from a single parent (and subsequently confirmed using PR Verify) should ever be delivered via PR to a device.

Step 6: Modifying a Design Source or Options

The Vivado IDE tracks dependencies between design runs. This is a critical feature for Partial Reconfiguration given the interdependencies of configurations. If any aspect of the parent configuration or implementation results are modified, it and all children must be recompiled.

1. Select the **impl_1 design** run.
2. In the Options tab of the Run Properties window, change the Strategy to **Performance_Explore**.

A pop-up dialog will alert you to the fact that impl_1 will be forced out of date if you proceed.

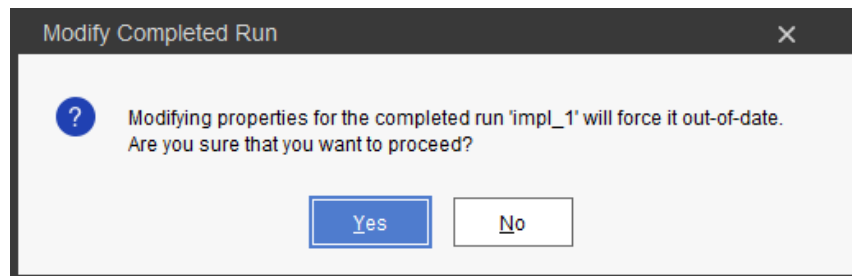

Figure 42: Modifying a Completed Run

3. Click **Yes**.

Multiple runs are now marked out-of-date: impl_1 and both child runs that depend on it. The resulting files still exist in their respective folders, but will be deleted as soon as the parent run is launched. The impl_greybox design run, on the other hand, remains completed as it does not depend on impl_1 as a parent.

Note that the Strategy option for each of the child runs remains at **Vivado Implementation Defaults**; child runs do not inherit options from the parent run. However, any strategy or option in child runs will only have an effect on the Reconfigurable Module implementation, as the static design is already routed and locked.

Name	Configuration	Constraints	Status	WNS	TNS	WHS	THS
synth_1 (active)		constrs_1	synth_design Complete!				
impl_1 (active)	config_right	constrs_1	Implementation Out-of-date				
child_0 (inactive)	config_left	constrs_1	Implementation Out-of-date	8.254	0.0...	0.079	0.0...
child_1 (inactive)	config_right_slow	constrs_1	Implementation Out-of-date	8.254	0.0...	0.079	0.0...
impl_greybox	config_greybox	constrs_1	route_design Complete!	8.741	0.0...	0.077	0.0...
Out-of-Context Module Runs							
shift_right_synth_1		shift_right	synth_design Complete!				
shift_left_synth_1		shift_left	synth_design Complete!				
shift_right_slow_synth_1		shift_right_slow	synth_design Complete!				

Figure 43: Design runs reset after parent modification

- In the Flow Navigator click **Run Implementation**.

A dialog will appear to confirm if you want to reset runs before continuing. Because the stale step is the first step in the parent run, the first options completely reset both parent and all child runs to the beginning of implementation. Click either **Reset and Re-run** or **Run from Step: phys_opt_design** to continue.

Figure 44: Reset and Re-run

This implements all three runs. First, the parent impl_1 run will complete, then the two child runs will run in parallel.

Conclusion

The Partial Reconfiguration Project Flow allows a great deal of flexibility, enabling users to manage their design environment and explore different options. Users must remain careful to track implementation results and bitstreams to ensure that only compatible bitstreams, built from a single fixed static image, are downloaded to the target device.

Lab 4: Vivado Debug and the PR Project Flow

Overview

This lab covers more project-based features for the Partial Reconfiguration (PR) solution. The following topics are covered in this lab:

- The Partial Reconfiguration project flow in the Vivado® IDE
- Current IP support within Reconfigurable Modules (RM)
- Inserting Vivado Debug cores within Reconfigurable Modules
- Improvements to reporting unique to Partial Reconfiguration
- Debugging within the Vivado Hardware Manager

It differs from the PR flow in Lab 3 in that while this Project Flow does not show greybox implementation and a few other features, it covers IP and debugging. This lab supports the following development platforms:

- KCU105 (Kintex™ UltraScale™)
 - VCU108 (Virtex™ UltraScale)
 - KCU116 (Kintex UltraScale+™)
 - VCU118 (Virtex UltraScale+)
-

Step 1: Loading Initial Design Sources

The first unique step in any PR design flow (project based or otherwise) is to define the parts of the design to be marked as reconfigurable. This is done via context menus in the **Hierarchical Source View** in project mode.

1. Extract the design from the TSC archive. The `pr_project_debug` data directory is referred to in this tutorial as the `<Extract_Dir>`.
2. Open the Vivado IDE and select **Create Project**, then click **Next**.
3. Select the `<Extract_Dir>` as the **Project location**. Leave the **Project name** as `project_1`, and leave the **Create project subdirectory** option checked. Click **Next**.
4. Select **RTL Project** and ensure the **Do not specify sources** checkbox is unchecked, then click **Next**.

5. Click the **Add Files** button and select these sources to add to the design:

- o <Extract_Dir>\Sources\hdl\top.v
- o <Extract_Dir>\Sources\hdl\multiplier\mult.v
- o <Extract_Dir>\Sources\ip\<board>\clk_wiz\clk_wiz_0.xci
- o <Extract_Dir>\Sources\ip\<board>\vio\vio_0.xci

Do not select add.v or mult_no_ila.v (in the adder and multiplier_without_ila folders, respectively), as these are the sources for RMs that will be added later.

6. Select the **Copy sources into project** checkbox.

7. Click **Next** to get to the Add Constraints window, then select the following file:

<Extract_Dir>\Sources\xdc\top_io_<board>.xdc

8. Select the Copy constraints files into project checkbox.

Note: These constraint files are full design constraints, scoped to the top level design. This constraint file does not include a floorplan.

9. Click **Next** to choose the part. In the Part selector, click on **Boards** and (using filters if needed) choose the appropriate target platform:

- o Kintex UltraScale KCU105 Evaluation Platform
- o Virtex UltraScale VCU108 Evaluation Platform
- o Kintex UltraScale+ KCU116 Evaluation Platform
- o Virtex UltraScale+ VCU118 Evaluation Platform

10. Then click **Next** and then **Finish** to complete project creation. The Sources window shows a standard hierarchical view of the design.

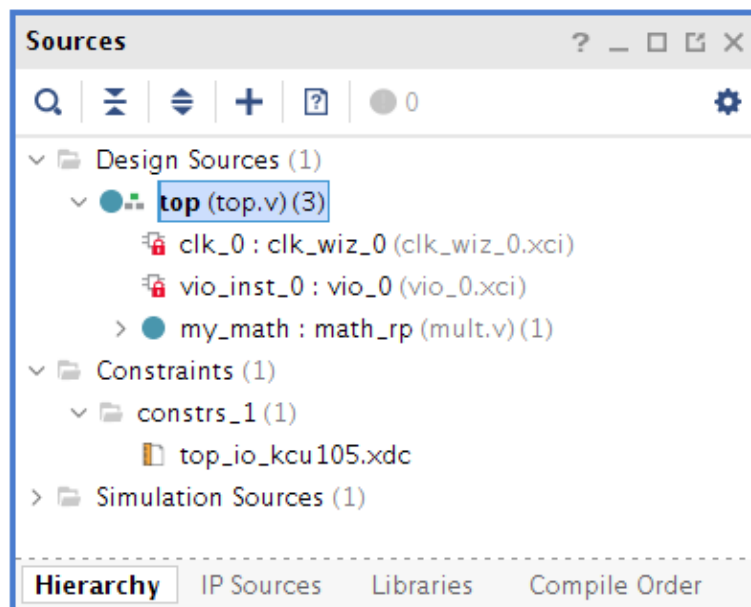

Figure 45: Sources view after project creation

At this point, a standard project is open. Nothing specific to Partial Reconfiguration has been done yet. Next, you will add an ILA core.

11. In the Flow Navigator, under Project Manager, open the IP Catalog and navigate to **Debug & Verification > Debug**.
12. Open the **ILA (Integrated Logic Analyzer)** IP core. Customize an IP with these non-default options on the **General Options** and **Probe_Ports(0..0)** tabs :
 - o Component Name: **ila_mult**
 - o Input Pipe Stages: **1**
 - o Probe Width of PROBE0: **8**

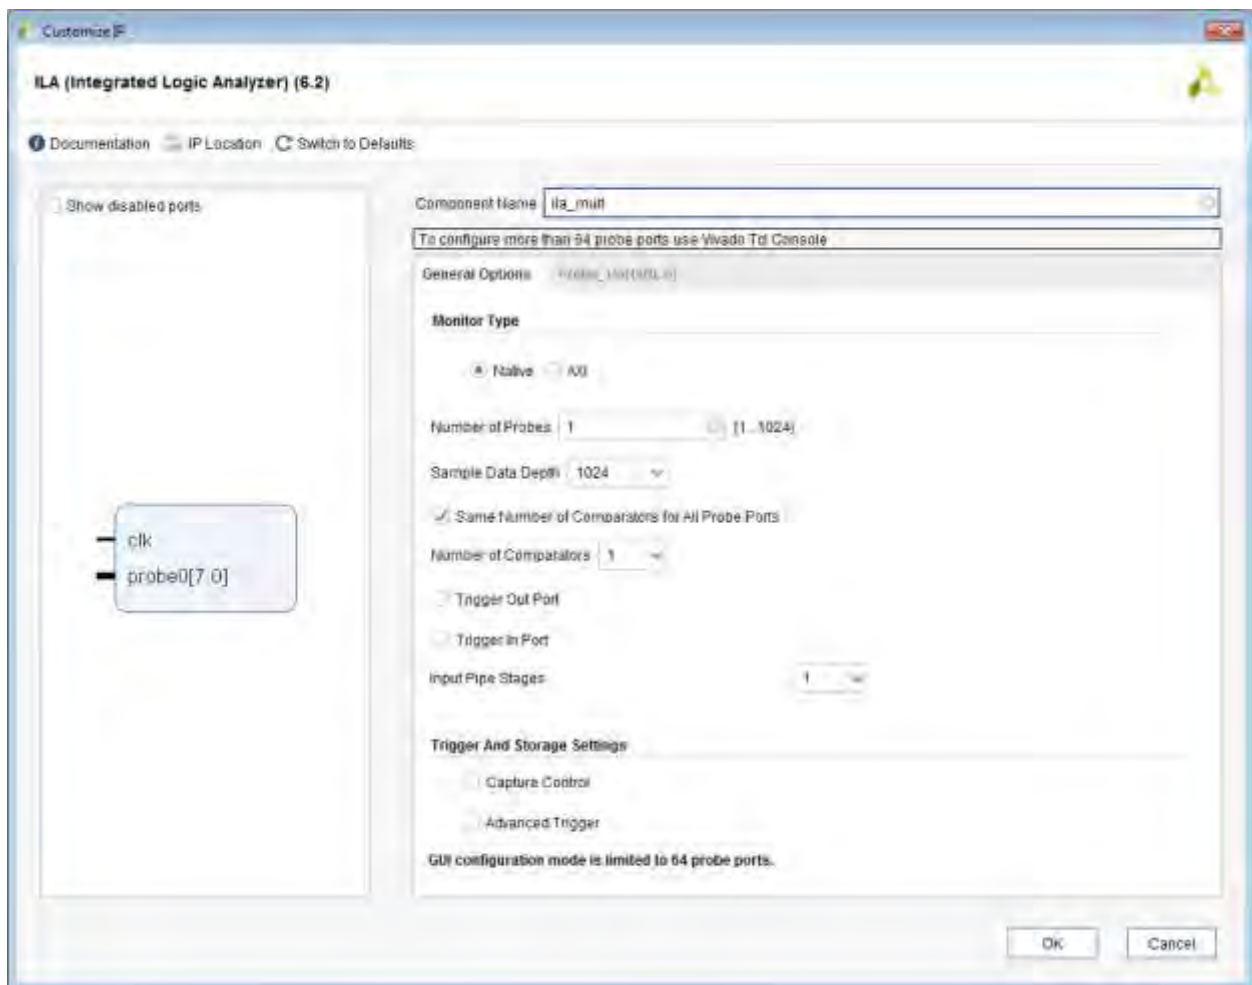

Figure 46: ILA customized for the Multiplier function

13. Click **OK** and then **Skip** to create the IP.

Do not select **Generate**. Leave the Synthesis Options set to **Out of context per IP**.

This IP now fills in underneath the **my_math** hierarchy. The ILA core monitors the multiply function. You have now completed a full design hierarchy.

Step 2: Setting Up the Design for Partial Reconfiguration

1. Select Tools > Enable Partial Reconfiguration

This prepares the project for the PR design flow. Once this is set it cannot be undone, so Xilinx recommends archiving your project before selecting this option.

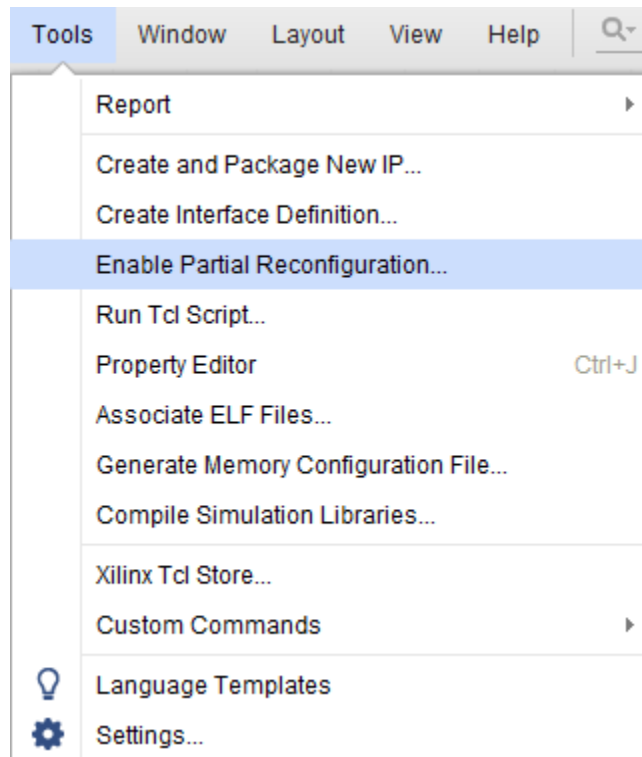

Figure 47: Enabling Partial Reconfiguration

In the ensuing dialog box, click **Convert** to turn this project into a PR project.

2. Right-click on the **my_math** instance in the sources window and select the **Create Partition Definition...** option.

This defines this instance as a Reconfigurable Partition in the design. Out-of-context synthesis is run to keep this module separated from top, and the post-synthesis checkpoint is used for the math_rp instance..

TIP: If there are multiple instantiations of a module within a design, each are marked as reconfigurable. If they all do not need to be reconfigurable, then the modules must be manually modified to remain unique. Then you can independently tag desired instances as Reconfigurable Partitions.

Note: Starting in Vivado 2018.3, IP placed within Reconfigurable Modules can be synthesized as Global or Out-of-Context. For this lab, leave the ILA IP set as the default of Out-of-Context.

- In the dialog box that appears, name both the Partition Definition and the Reconfigurable Module.

The Partition Definition is the general reference for the workspace into which all Reconfigurable Modules will be inserted, so give it an appropriate name: **math**.

The Reconfigurable Module refers to this specific RTL instance, so give it a name that references its functionality: **mult**.

- Then click **OK**.

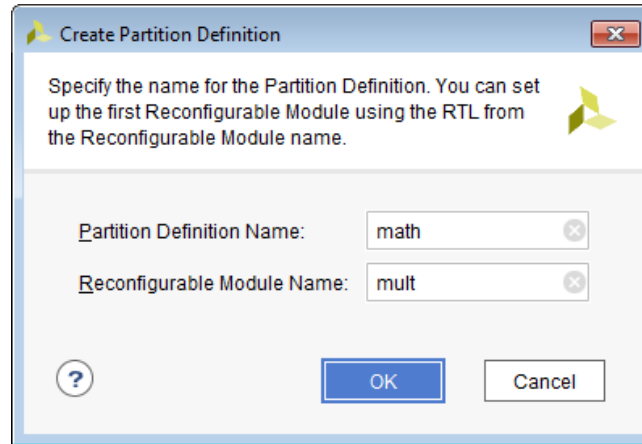

Figure 48: Creating the math Partition Definition

The Sources view has now changed slightly, with the **my_math** instance now shown with a yellow diamond, indicating it is a Partition. The **Partition Definitions** tab in this window shows the list and contents of all Partition Definitions (just one in this case) in the design. In addition, an out-of-context module run has been created for synthesizing the **mult** module.

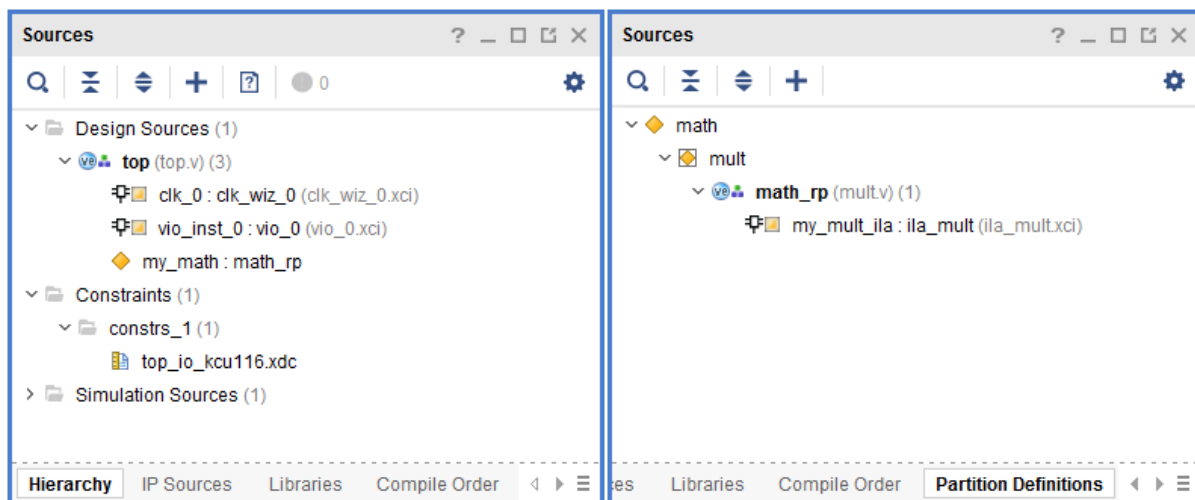

Figure 49: Sources views after the math partition has been defined

At this point, new Reconfigurable Modules may be added (or modified) via the Partial Reconfiguration Wizard.

IMPORTANT: After Partitions have been defined, all additional RMs must be added via the Partial Reconfiguration Wizard, and any management of RM sources, configurations, and runs must also be done via this wizard.

Step 3: Using the Partial Reconfiguration Wizard to Complete the Rest of the Design

1. Launch the **Partial Reconfiguration Wizard** by selecting this option under the Tools menu or from the Flow Navigator.
2. Click **Next** to get to the Edit Reconfigurable Modules page. Here you can see the mult RM already exists, and there are add, remove and edit buttons on the left hand side of the page. Click on the + icon to add a new RM.

3. Click the **Add Files** button to select the top level of the add function:

```
<Extract_Dir>\Sources\hdl\adder\add.v
```

If module-level constraints were needed, they would be added here. Note that they would need to be scoped to the level of hierarchy for this Partition.

4. Select `add.v` either by double-clicking or by single-clicking and selecting **OK**.
5. Fill in the Reconfigurable Module field to be **add**. Set the Partition Definition to be **math**, leave Top Module Field empty and the **Sources are already synthesized** option unchecked. Select the **Copy sources into project** checkbox. Click **OK** to create the new module.

Two Reconfigurable Modules are now available for the math Reconfigurable Partition.

Figure 50: Partial Reconfiguration Wizard with two Reconfigurable Modules defined

6. Click **Next** to define configurations.
7. Let the Wizard create the configurations by selecting the **automatically create configurations** link.

Configurations are full design images consisting of the static design and one RM per RP. You can either create any desired set of configurations, or simply let the wizard select them for you, as you did above.

The minimum set of two configurations is now created. The math instance has been given **mult** in the first configuration and **add** in the second configuration.

Note: The Configuration Name is editable – in Figure 51 the names have been updated to **config_mult** and **config_add** to reflect the Reconfigurable Modules contained within each configuration.

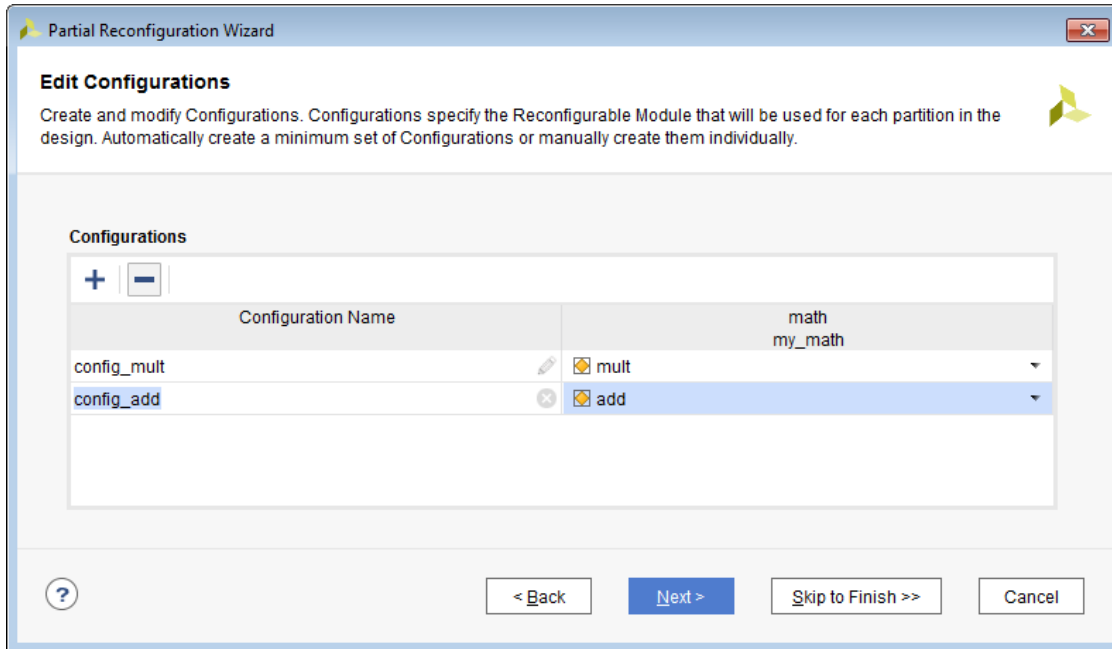

Figure 51: Auto-Generated minimum set of Configurations with modified names

Additional configurations can be created by using these two Reconfigurable Modules when desired. Greybox (blackbox with LUT tie-offs) configurations can also be selected, but this feature is not used in this lab.

- Click **Next** to get to the Edit Configuration Runs page.

As with configurations themselves, the runs used to implement each configuration can be automatically or manually created. A parent-child relationship will define how the runs interact – the parent run implements the static design and all RMs within that configuration, then child runs reuse the locked static design while implementing the RMs within that configuration in that established context.

- Click on the **automatically create configuration run** link to populate the Configuration Runs page with the minimum set of runs.

This creates two runs, consisting of one parent configuration (config_mult) and one child configuration (config_add). Any number of independent or related runs can be created within this wizard with options for using different strategies or constraint sets for any of them. For now, leave this set to the two runs set here. Note that the names of the runs are not editable.

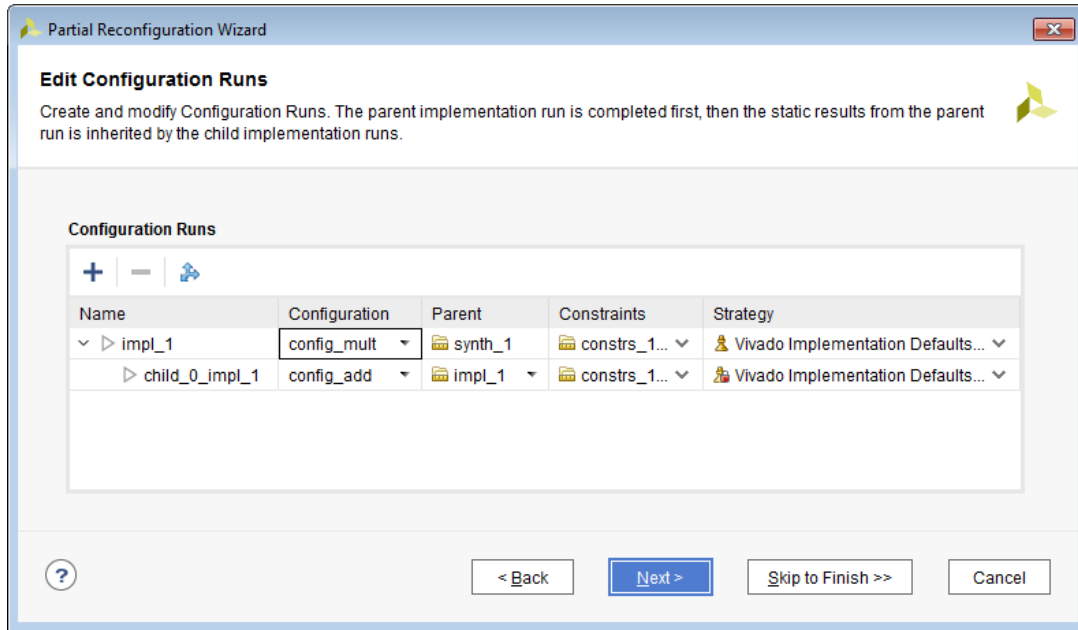

Figure 52: Auto-generated minimum set of Configuration Runs

- Click **Next** to see the Summary page then **Finish** to complete the setup and exit the Wizard.

IMPORTANT: Nothing is created or modified until you click Finish to exit the Partial Reconfiguration Wizard. All actions are queued until this last click, so it is possible to step forward and back as needed without implementing changes until you are ready.

Back in the Vivado IDE, the Design Runs window has been updated. A second out-of-context synthesis run has been added for the math RM, and a child implementation run (child_0_impl_1) has been created under the parent (impl_1).

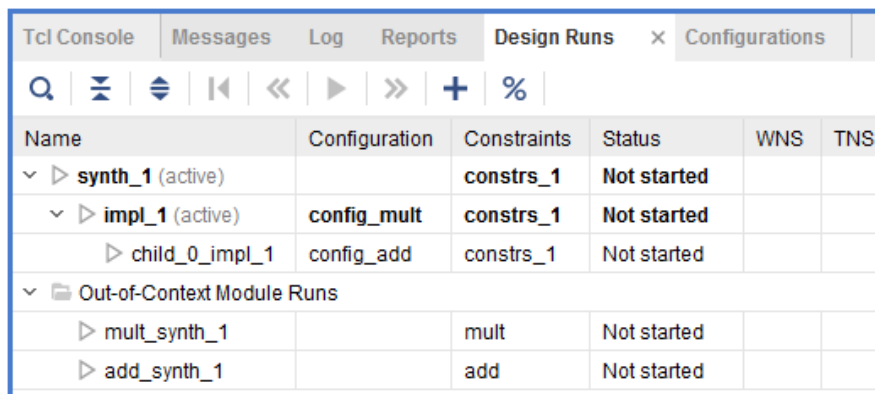

Figure 53: Design Runs window showing all synthesis and implementation ready to launch

Step 4: Adding IP within the Reconfigurable Module

Looking back at the Partition Definitions tab, expand the added RM **math_rp** to see that there are three submodules that must be added to complete its functionality, as indicated by the question mark icons.

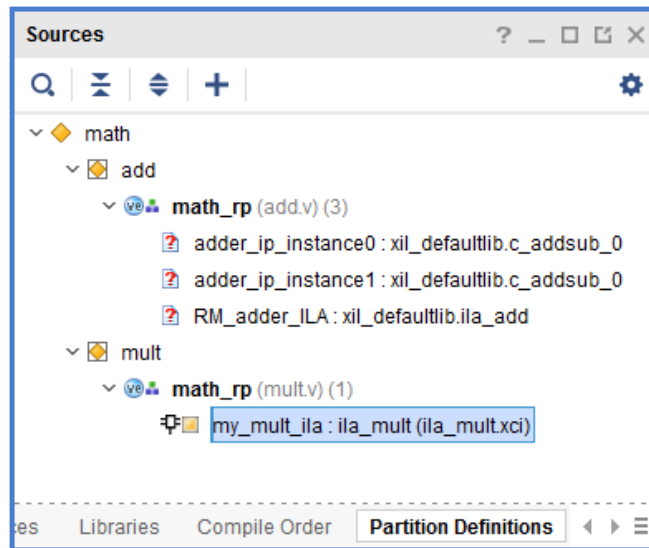

Figure 54: Partition Definitions tab with missing sources for add

All three of these missing modules are IP. The IP instances must be unique within each RM, so the same ILA core instance cannot be used from static or another RM.

1. Right-click on the **ila_mult** instance within the **mult** RM and select **Copy IP**.
2. Set the Destination IP Name to `ila_add` and leave the Destination IP Location as is, then click **OK**.

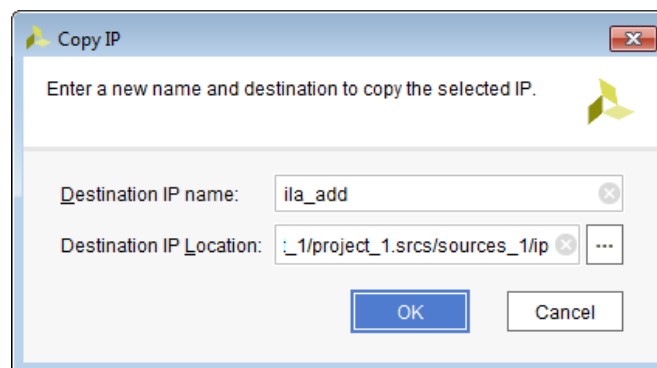

Figure 55: Copying the ILA from math to add

This copied IP will be placed in the main Sources hierarchy window in the primary design filesset, so it must be moved to the **add** RM blockset.

3. In the Hierarchy tab, right-click on the **ila_add** instance and select **Move to Reconfigurable Module**. Select the **add** RM and click **OK**.

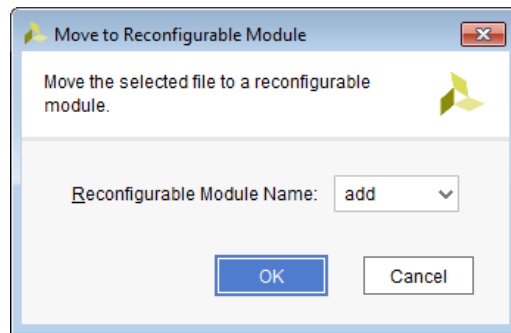

Figure 56: Moving IP to an RM

If you navigate back to the partitions definitions tab, you'll see the ILA IP instance was properly moved under the add RM.

4. Open the IP Catalog and search on **add** to find the **Adder/Subtractor** IP. Open this IP and customize it with these non-default options, leaving the name set to `c_addsub_0`:
 - Input Type: **Unsigned** (for both A and B)
 - Input Width: **5** (for both A and B)
 - Output Width: **6**
 - Latency: **0**
 - Uncheck the **Clock Enable** on the Control tab
5. Click **OK**.

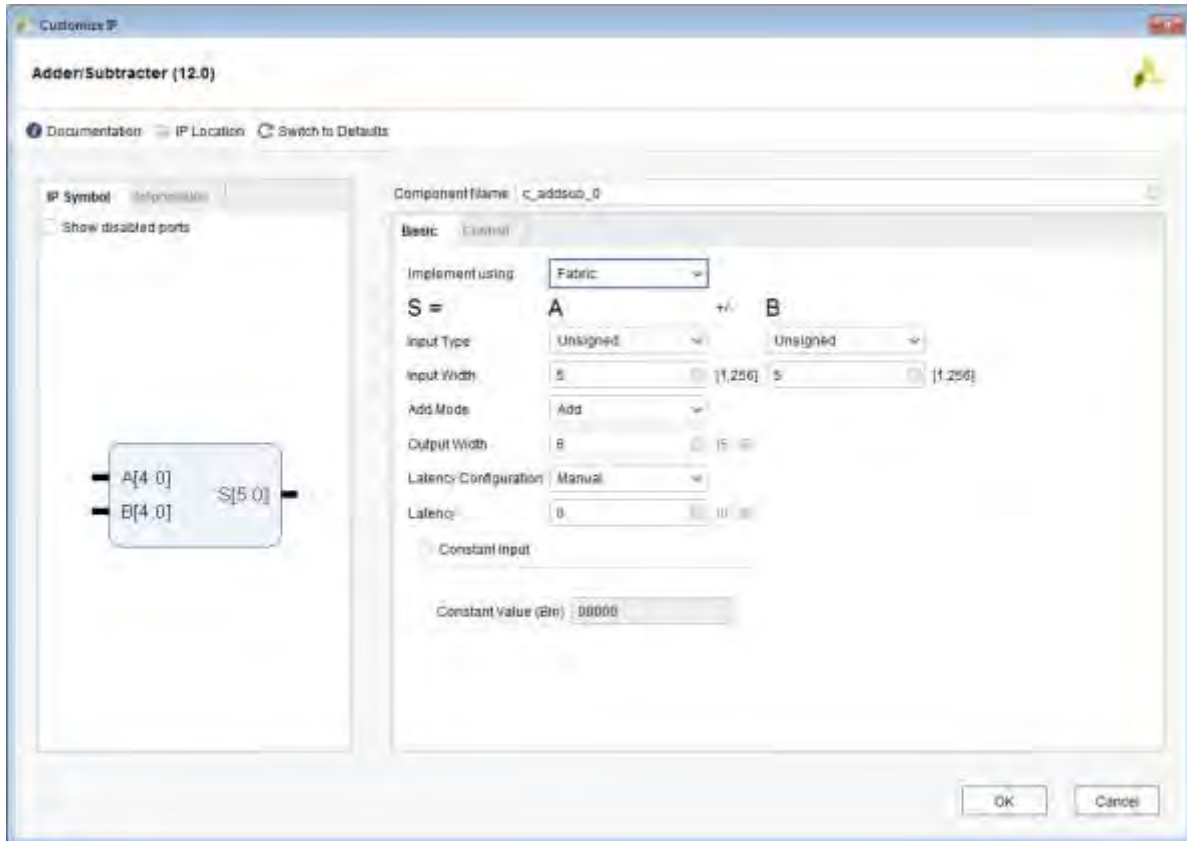

Figure 57: Customizing the Adder/Subtractor IP

6. Click **Skip** to complete IP generation.

Like with the ILA IP, this has been added to the main source set, so follow the same procedure to move it to the add RM.

7. In the Hierarchy tab of the Sources window, right-click on the **c_addsub_0** instance and select **Move to Reconfigurable Module**.

Select the **add** RM and click **OK**.

Note that this IP is used for both adder function instances within the add RM. At this point, the entire design has been loaded, and you are ready to move on to implementation.

Step 5: Synthesizing the Design and Creating a Floorplan

Before launching synthesis, take a look at the naming convention that inserts the Debug Hubs necessary for the Vivado Debug solution.

1. Open `mult.v` and examine the port list in this file.

The port list includes twelve ports that start with `S_BSCAN_`. These ports are used to connect the Debug Hubs that are inserted in the static and reconfigurable parts of the

design. The insertion of these hubs is automatic. Connections are automatically made as long as the port list matches this naming convention.

CAUTION! These **exact** port names must be used to have the inference occur. If the port names differ at all, then the attributes shown in the comments of these RTL files must be used to assign the new signal names to the debug properties as indicated.

With the design from section one open in the Vivado IDE, take a look at the Design Runs window. The top-level design synthesis run (synth_1) and the parent implementation run (impl_1) are marked "active." The Flow Navigator actions apply to these active runs, so clicking on Run Synthesis or Run Implementation will pull the design through only these runs, as well as the OOC synthesis runs needed to complete them. You could select the child implementation run, right-click, and select Launch Runs to pull through the entire flow, but we'll run synthesis separately here.

2. In the Flow Navigator, click **Run Synthesis**. When synthesis completes, select **Open Synthesized Design**.

This action synthesizes all OOC modules, followed by synthesis of the top level design. This is no different than any design with OOC modules (IP or otherwise).

3. Open the schematic for the post-synthesis view to see the insertions performed during synthesis.

In the top level design, see that a **dbg_hub** instance was inserted. Its `sl_*` ports are connected to the VIO debug core at the top level. Next, descend into the **my_math** hierarchy to see that another **dbg_hub** instance has been inserted, with its `sl_*` ports connected to the ILA debug core in that module. Note that this Reconfigurable Module is the multiplier, as this is the schematic view of the active parent run.

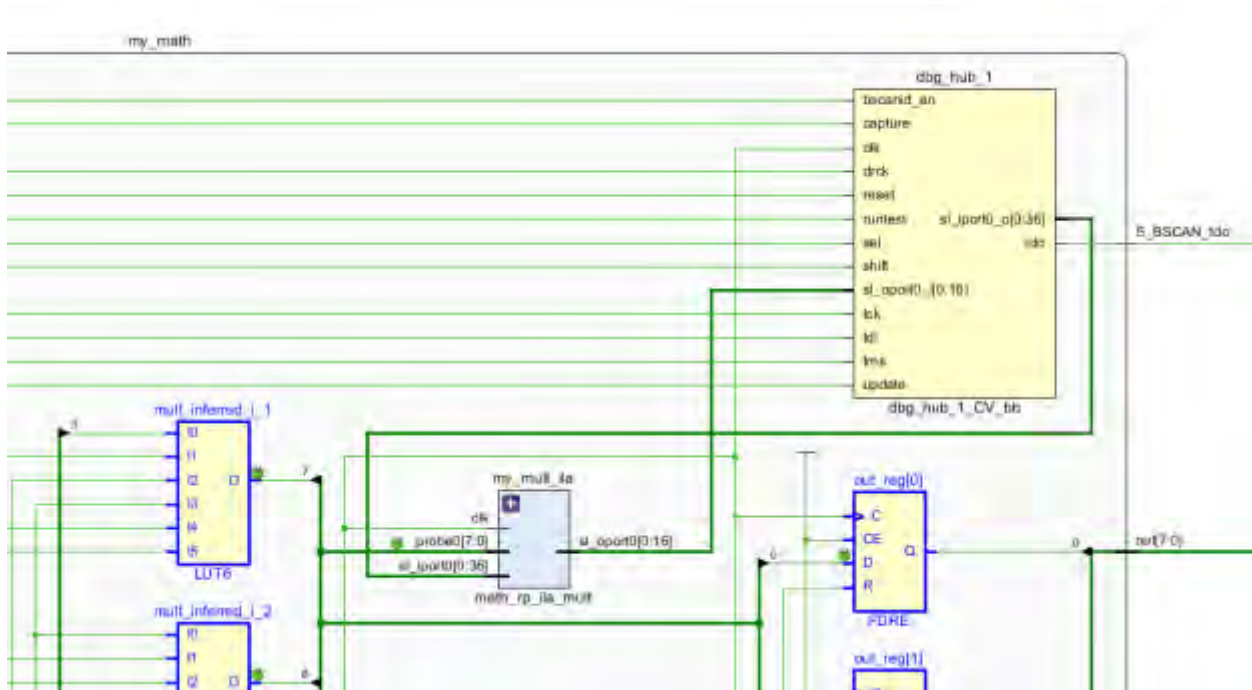

Figure 58: dbg_hub_1 inserted within the mult RM

4. Select **Layout > Floorplanning** to put Vivado in floorplanning mode. Then in the Netlist window, right click on the **my_math** instance and select **Floorplanning > Draw Pblock**. Create a Pblock wherever you'd like. In the dialog box that appears, keep the name **pblock_my_math** and leave only SLICE, DSP and BRAM resource types checked.

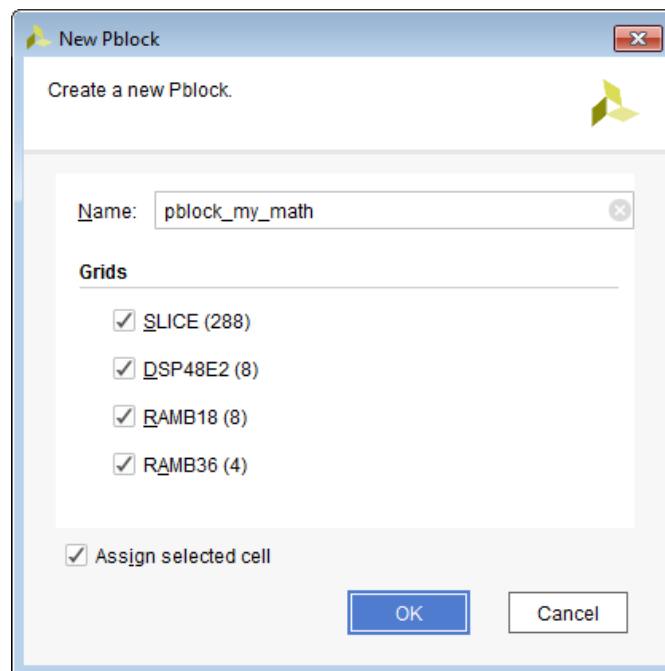

Figure 59: Drawing a Pblock for the my_math RP

If the region you have selected does not have enough resources of any particular type, these resource types will appear in red in the Statistics tab of the Pblock Properties window. Make adjustments as necessary, then save the floorplan. Remember, each RM contains an ILA core, which will require BRAM. Also, this design has a high number of control sets, so the region required may be a little bigger than expected. An area of at least 3000 CLBs plus a column of BRAM is suggested.

- Run PR-specific design rule checks by selecting **Reports > Report DRC**. To save time, you can deselect all checkboxes other than the one for Partial Reconfiguration. Click **OK** to run.

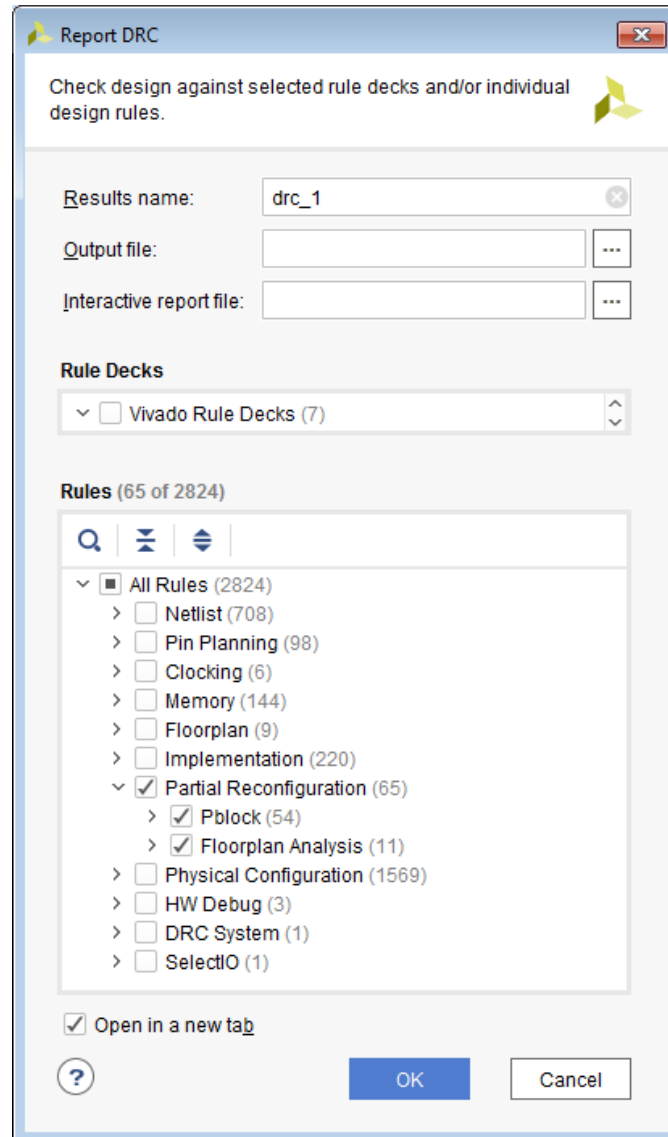

Figure 60: Checking Partial Reconfiguration DRCs

Fix any errors that may appear. Advisory messages might appear for certain devices with suggestions on how to improve the quality of the given Pblocks.

TIP: Run Partial Reconfiguration Design Rule Checks early and often.

6. Save your constraints by clicking **Save Constraints** in the top toolbar.

Step 6: Running the PR Configuration Analysis Report

The PR Configuration Analysis tool compares each Reconfigurable Module that you select to give you input on your PR design. It examines resource usage, floorplanning, clocking, and timing metrics to help you manage the overall PR design. The PR Configuration Analysis tool is run through the Tcl Console.

1. In the Tcl Console, `cd` into the project directory. Next, enter this command to run a report on the two RMs available in this design:

```
report_pr_configuration_analysis -cells my_math -dcps
{./project_1.runs/add_synth_1/math_rp.dcp ./project_1.runs/mult_synth_1/math_rp.dcp}
```

Note: If your project is not named "project_1" you'll need to adjust this in the Tcl command.

This runs the analysis with the default settings, gathering data for the first three focus areas listed below. Use the `-help` option to see that you can focus on three specific areas.

- o The `-complexity` switch focuses the report on resource usage, including the maximum resources required for the RP.
- o The `-clocking` switch focuses the report on clock usage and loads for each RM.
- o The `-timing` switch focuses the report on boundary interface timing details.
- o The `-rent` switch adds rent metrics to the report, but can take a long time to run.
- o The `-file` switch redirects the report to a file.

Examining the report in the Tcl Console, you will see a Complexity summary in section 2. It shows the current RM (the multiplier), RMs 1 and 2 (the adder and multiplier, respectively), and a column for the maximum. This table examines the resource utilization of each module to find the maximum of each so you can construct Pblocks appropriately.

Note that the resource counts of RM1 and RM2 appear to be low. Above the report in the log you will see a few critical warnings:

```
CRITICAL WARNING: [Project 1-486] Could not resolve non-primitive black
box cell 'math_rp_c_addsub_0' instantiated as 'adder_ip_instance0'
```

The post-synthesis checkpoints do not include the submodule IP as those were generated out-of-context. In order to see the complete picture of each RM, these lower-level checkpoints must be linked in, or the IP must be synthesized set to Global.

2. In the Partition Definitions tab, expand the hierarchy if necessary to be able to right click on the **my_mult_ila** IP and select **Generate Output Products**.

3. Change the **Synthesis Options** value to **Global**, then click **Apply** and then **Cancel**.
4. Repeat this process for both IP under the adder module, **my_add_ila** and **adder_ip**. The latter has two instances but this process only needs to happen once, as the IP instances are identical.
5. Synthesis for these modules are now out of date. Select **Run Synthesis** in the Flow Navigator. Accept all the dialogs that ask about resetting and resynthesizing all runs.
6. When synthesis completes, rerun the `report_pr_configuration_analysis` command from step 1 and examine the log and results.

Step 7: Implementing the Design

1. In the Flow Navigator, select **Run Implementation** to run place and route on all configurations.

This action runs implementation first for `impl_1` and then for `child_0_impl_1`. In addition to running place and route for the two runs with all the PR requirements in place, it does a few more tasks specific to PR. After `impl_1` completes, Vivado automatically:

- Writes a module-level (OOC) checkpoint for the routed multiplier RM.
- Carves out the logic in the RP to create a static-only design image. This is done by calling `update_design -black_box` for the RP instance.
- Locks all placement and routing for this static-only design. This is done by calling `lock_design -level routing`.
- Saves this locked static parent image to be reused for all child runs.

In addition, when the child run completes, a module-level checkpoint is created for the routed adder RM. A locked static design image would be identical to the parent, so this step is not necessary.

In Vivado projects, dependency management is handled by the Vivado IDE. If sources are modified, any applicable runs will be marked out-of-date. The parent-child relationship means these checks must understand dependencies. For example, if **add.v** is modified, only its OOC synthesis run and the child implementation run would be marked out of date.

If only specific configuration runs are desired, these can be individually selected within the Design Runs window. Note that a parent run must be completed successfully before a child run can be launched, as the child run starts by importing the locked static design from the parent.

Name	Configuration	Constraints	Status	WNS	TNS	WHS
✓ synth_1 (active)		constrs_1	synth_design Complete!			
✓ impl_1 (active)	config_mult	constrs_1	route_design Complete!	6.052	0.0...	0.013
✓ child_0_impl_1	config_add	constrs_1	route_design Complete!	5.771	0.0...	0.013
Out-of-Context Module Runs						
✓ mult_synth_1		mult	synth_design Complete!			
✓ add_synth_1		add	synth_design Complete!			

Figure 61: Both Configurations routed

- When the implementation runs complete, click **Open Implemented Design** in the resulting pop-up dialog.

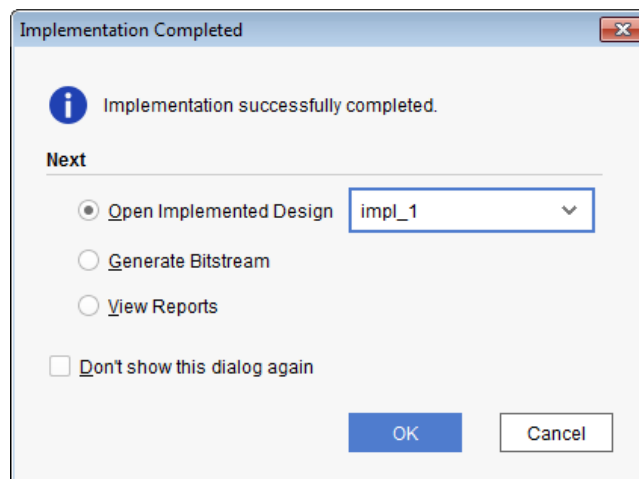

Figure 62: Open the impl_1 Configuration

CAUTION! Even though the design has been processed through to the child implementation run, selecting **Open Implemented Design** opens the parent run by default. Use the pulldown selection to choose the desired implementation run.

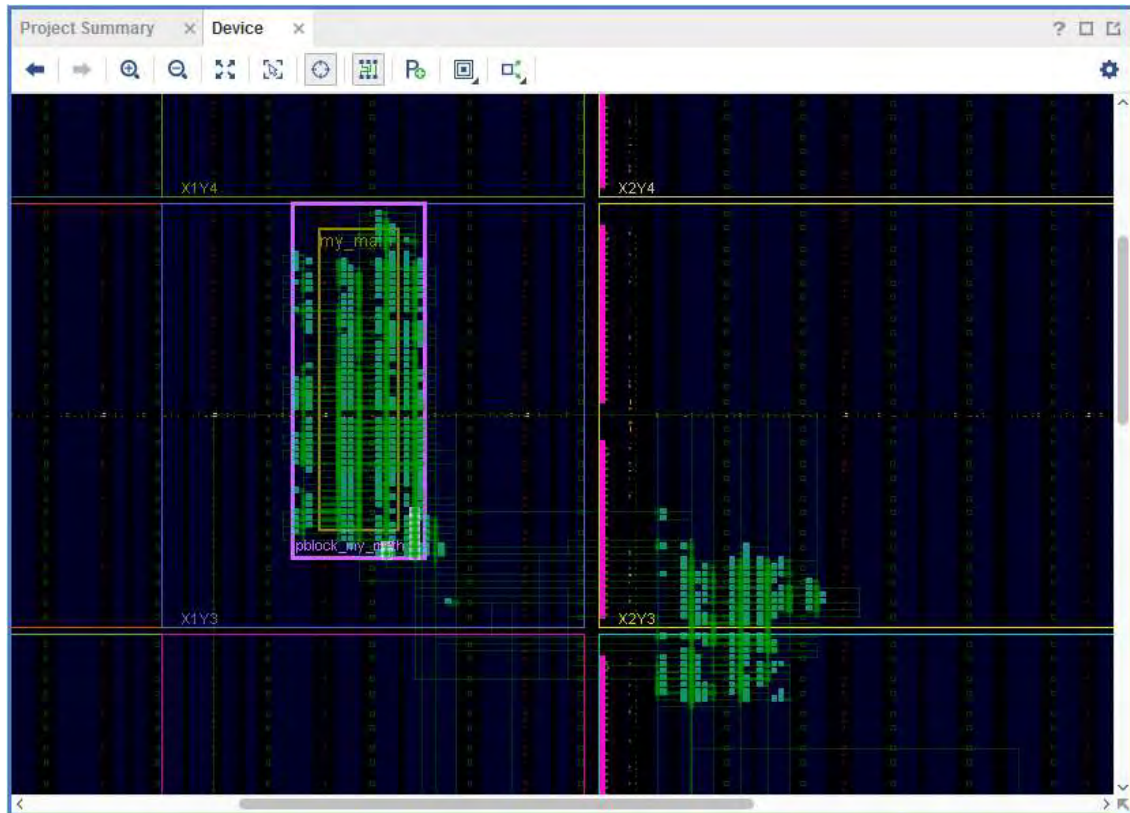

Figure 63: Device view of the routed parent design

This is the routed design for the multiplier configuration. Next, take a look at the frameset of the placement and routing areas.

3. In the Tcl Console, `cd` to the current project directory (if you are not already there). Then run these commands to source visualization scripts:

```
source project_1.runs/impl_1/hd_visual/pblock_my_math_Routing_AllTiles.tcl
highlight_objects -color yellow [get_selected_objects]
```

This first Tcl script identifies the frames that are valid for routing the reconfigurable part of the design. Note that it extends to the height of the clock region(s) occupied by the Pblock, and extends left and right by two programmable units. (Programmable units are pairs of resource columns.)

- Run these commands to identify the frameset used for placing the reconfigurable part of the design.

```
source project_1.runs/impl_1/hd_visual/pblock_my_math_Placement_AllTiles.tcl
highlight_objects -color blue [get_selected_objects]
```

This highlighted region will be either the Pblock area itself, or an area just smaller than the Pblock if the Pblock did not align with programmable units boundaries.

Your device view should look something like this:

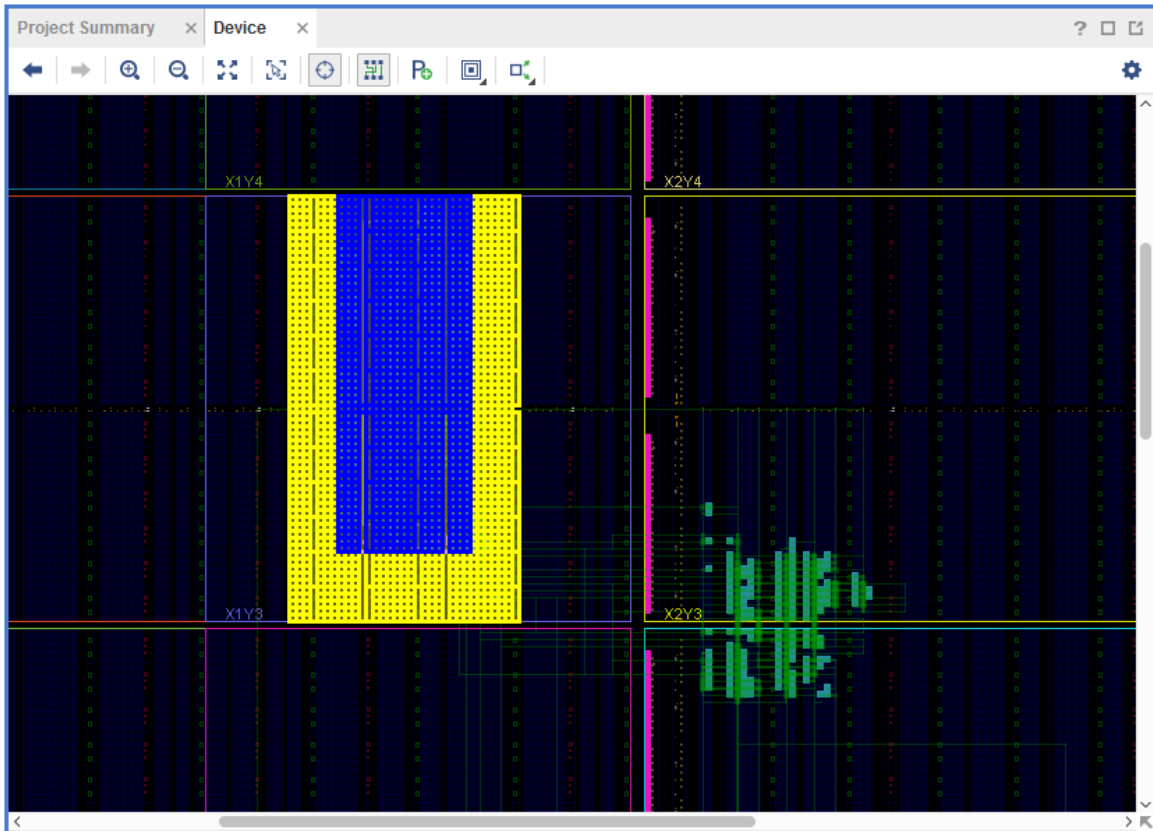

Figure 64: The math RP highlighted to show placement (blue) and routing (yellow) boundaries

Static logic may be placed in the expanded routing region, which is now the remaining yellow region. Static routing can use any resources in the device.

- In the Flow Navigator, select **Report Timing Summary** and click **OK** to analyze the design timing.
- In the Timing tab, select the **Design Timing Summary** and click on the value for the Worst Negative Slack (WNS) to bring up the top ten worst paths. Double-click on the first path to open the timing summary on that path.

In this timing report, note that in the Clock Paths and the Data Path, there is a new column labeled Partition that shows which partition (or boundary) that particular part of the path is in.

CAUTION! You might need to toggle the visibility of the Partition column by right-clicking on the table header and checking **Partition**. Then expand the timing report window or adjust the column widths to see the Partition column, the last column on the right.

Delay Type	Incr (ns)	Path	Location	FFlags	Netlist Resource(s)	Partition

Required Time		8.869				

Figure 65: Timing report path with partitions shown

7. Close the impl_1 implemented design with **File > Close Implemented Design**.

Step 8: Adding an Additional Reconfigurable Module and Corresponding Configuration

In this step, you will add a third RM and implement its configuration. This new RM is the same multiplier function but with the ILA instantiation commented out. Even though there are no debug cores in this module, the Debug-specific port names (and corresponding attributes if used) are still required for consistency across all RMs. These ports are tied off via LUTs much like the greybox flow.

CAUTION! Actual greybox configurations (blackbox RMs with LUT tie-offs) are not yet supported with the Debug Hub insertion flow.

1. Open the Partial Reconfiguration Wizard.
2. On the **Edit Reconfigurable Modules** page, click the + button to add a new RM.
3. Select the `mult_no_ila.v` file in `<Extract_Dir>\Sources\hdl\multiplier_without_ila`, name the Reconfigurable Module **mult_no_ila**, and then click **OK** and **Next**.

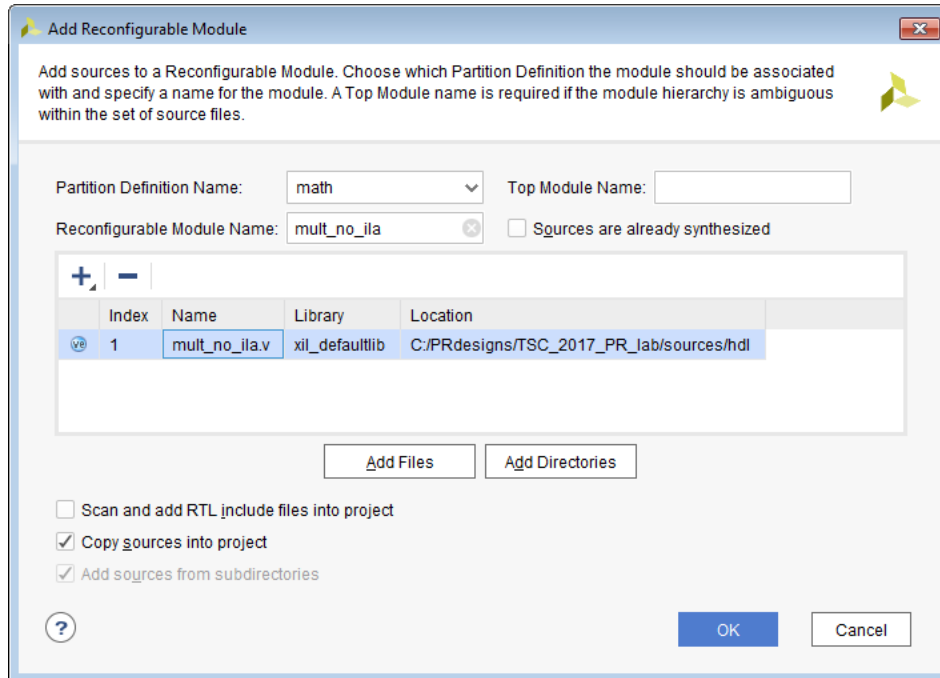

Figure 66: Adding a new RM mult_no_ila

Note that on the Edit Configurations page, there is no longer an option to automatically create configurations, as you already have two existing ones. You can re-enable this option by removing all existing configurations, but this recreates all configurations and removes all existing results.

4. Create a new configuration by clicking the + button, entering the name **config_mult_no_ila**, then clicking **OK**. Select **mult_no_ila** as the Reconfigurable Module.

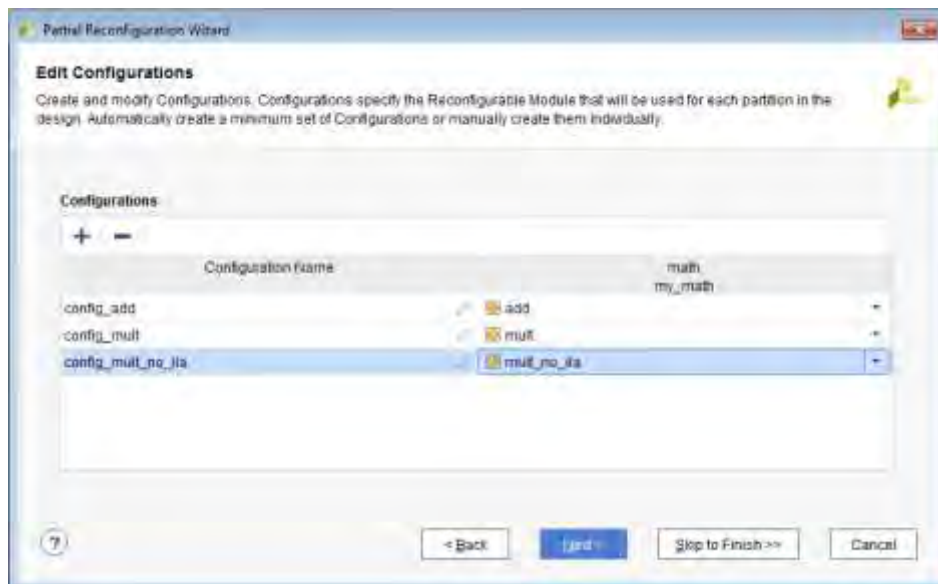

Figure 67: Creating the mult_no_ila configuration

5. Click **Next** to advance to the Configuration Runs. Use the + button to create a new configuration with these properties:
 - Run: **child_1_impl_1** – this matches the existing convention, although it can be named anything.
 - Parent: **impl_1** – this makes this configuration a child run of the existing parent run
 - Configuration: **config_mult_no_ila** – this is the one with the new RM

Click **OK** to accept this new configuration.

Figure 68: Creating a new Configuration Run

This new configuration, as a child of the existing impl_1, will reuse the static design implementation results, just like config_add did. Three runs now exist, with two as children of the initial parent. The green check marks indicate that two of the runs are currently complete.

Figure 69: The config_mult_no_ila configuration added as a new child run

- Click **Next** then **Finish** to build this new configuration run.

Name	Configuration	Constraints	Status	WNS	TNS
✓ synth_1 (active)		constrs_1	synth_design Complete!		
✓ impl_1 (active)	config_mult	constrs_1	route_design Complete!	6.052	0.000
✓ child_0_impl_1	config_add	constrs_1	route_design Complete!	5.606	0.000
▶ child_1_impl_1	config_mult_no_ila	constrs_1	Not started		
Out-of-Context Module Runs					
✓ mult_synth_1		mult	synth_design Complete!		
✓ add_synth_1		add	synth_design Complete!		
▶ mult_no_ila_synth_1		mult_no_ila	Not started		

Figure 70: New OOC synthesis run and Configuration run added

- Select this new child implementation run, right-click and select **Launch Runs**. This runs OOC synthesis on the mult_no_ila module, then implements this module within the context of the locked static design.

CAUTION! Do not select **Run Implementation** from the Flow Navigator. It will rerun all the implementation runs, even those that have completed.

8. Click **Cancel** on the dialog that opens after implementation completes.
Right-click on `child_1_impl_1` and select **Open Run**. In the device view note two things:
 - a. The static logic is locked and therefore appears orange.
 - b. In the **Design Runs** tab, notice that the amount of logic in the RP Pblock is much smaller than for the other configurations.
9. Select **Tools > Schematic** (or hit F4) to open the schematic view. Descend into the `math_rp` instance to see that all the BSCAN ports are tied to LUTs and no ILA or Dbg_Hub cores are inserted.

Step 9: Generating Bitstreams

At this point, there are two steps remaining: the first is running PR Verify to compare the two configurations to ensure consistency of the static part of the design images. This step is highly recommended and will occur automatically within the Vivado project. The second step is to generate the bitstreams themselves.

1. In the Flow Navigator, click **Generate Bitstream**. This action launches bitstream generation on the active parent run, and launches PR Verify and then bitstream generation on the implemented child runs.
2. This generates full and partial bitstreams for each configuration run.
3. When bitstream generation completes, select **Open Hardware Manager**.

Step 10: Connecting to the Board and Programming the FPGA

1. Open the hardware manager and connect to the target board.
This can be a local board or on a remote server. Exact details of how to accomplish this task depends on your setup. You can interact with this design remotely via the VIO and ILA debug cores.
2. Once you are connected to the hardware, right-click on the FPGA instance and select **Program Device**. The `top.bit` file should be selected by default from the `project_1.runs/impl_1` directory. If it is not, select `top.bit` from the `impl_1` project run directory. Note that the `top.ltx` probes file is automatically selected. This is a complete device bitstream that includes the multiplier RM.

3. Click on the **hw_vio_1** dashboard tab. If it is not visible, open **Dashboard Options** and check the **hw_vio_1** box.
4. Press the + button and select all the probes from the add probes dialog box, then click **OK**.

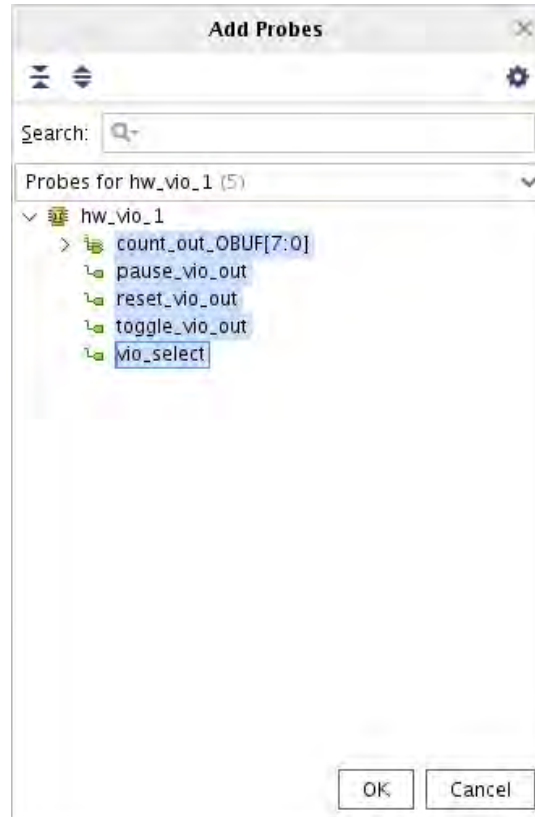

Figure 71: Selecting probes for debug

5. Right click on the probes and set them up in the following manner:
 - count_out_OBUF[7:0] bus – Radix: unsigned decimal
 - count_out_OBUF[7:0] individual bits – LED: low value Red, high value Green
 - pause_vio_out – Active High Button
 - reset_vio_out – Active High Button
 - toggle_vio_out – Active High Button
 - vio_select – Toggle Button

The resulting dashboard looks like this:

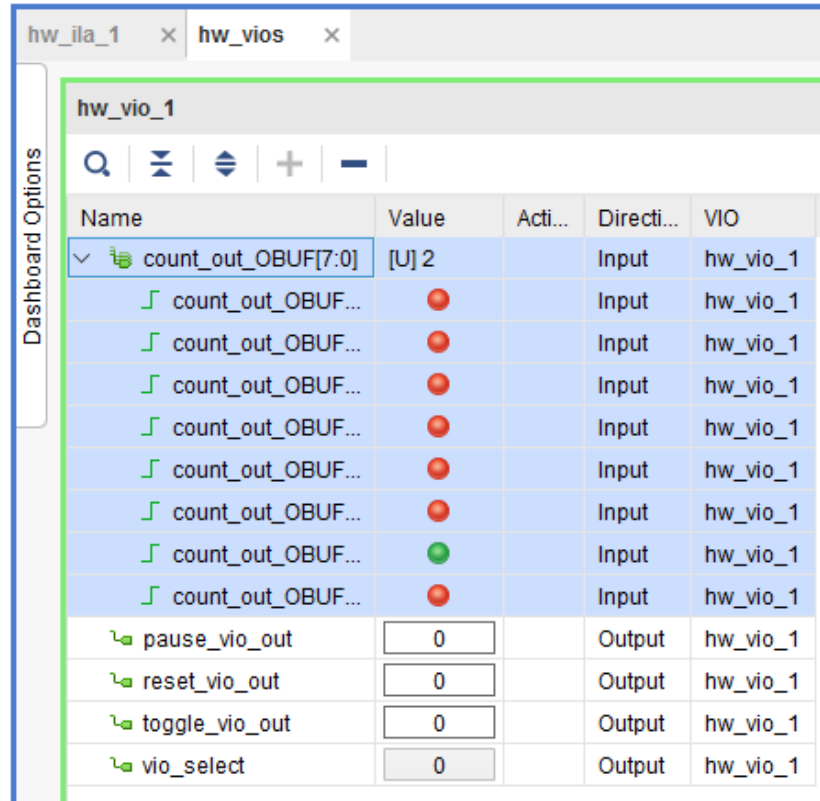

Figure 72: Initial VIO dashboard for debugging

- Change the `vio_select` value to a **1**. This disables the buttons on the physical board and enables the pause, reset and toggle buttons via the VIO.
- Select the **pause** button by clicking on the **Value** field of `pause_vio_out`. You will see the LED counter stop at a particular value. Take note of the unsigned binary value of the `count_out_OBUF`. In this screenshot, the value is 12.

Name	Value	Acti...	Directi...	VIO
count_out_OBUF[7:0]	[U] 12		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
count_out_OBUF...	●		Input	hw_vio_1
pause_vio_out	0		Output	hw_vio_1
reset_vio_out	0		Output	hw_vio_1
toggle_vio_out	0		Output	hw_vio_1
vio_select	1		Output	hw_vio_1

Figure 73: Monitoring the counter via VIO

- Press the **toggle_vio_out** button. The value of the count_out_OBUF bus be squared, as the current RM is a multiplier. In this case, 144.
- Press the **pause** button again and the counter will start. The count_out_OBUF values will now count by the square of 0 to 15. Ex. 1, 4, 9, 16, 25, etc.

Note: Given the relative frequencies of the internal clock and the sampling rate of the Hardware Manager, you may not see all values in the sequence.

- Press the reset button to return the design to its default state. This count resumes to its initial 0 to 15 range.
- Play with these buttons to understand the design. If you have a local board, you can toggle the vio_select and use the buttons on the board and the LEDs on the board to observe the same behavior.
- Switch to the ILA dashboard. Up to this point you have used the VIO located in the static design. You can see the result of the multiplier, but if you want to observe the waveforms inside the RM, you can do this with the ILA located there.
- In the Trigger Setup window, press the + button and add the **my_math/mult[7:0]** probes. Change the radix (in both the trigger setup and waveform windows) to unsigned decimal and set the value to 196 (i.e. 14x14).

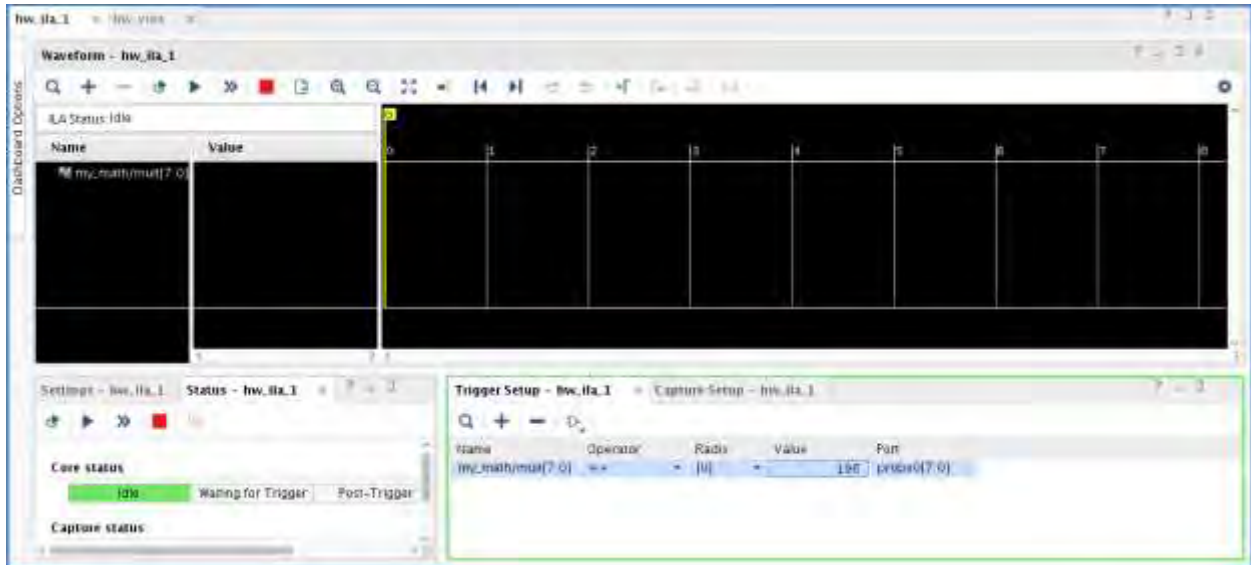

Figure 74: Defining probes within the mult RM

14. In the settings window for the ILA, change the trigger position in the window to 512.

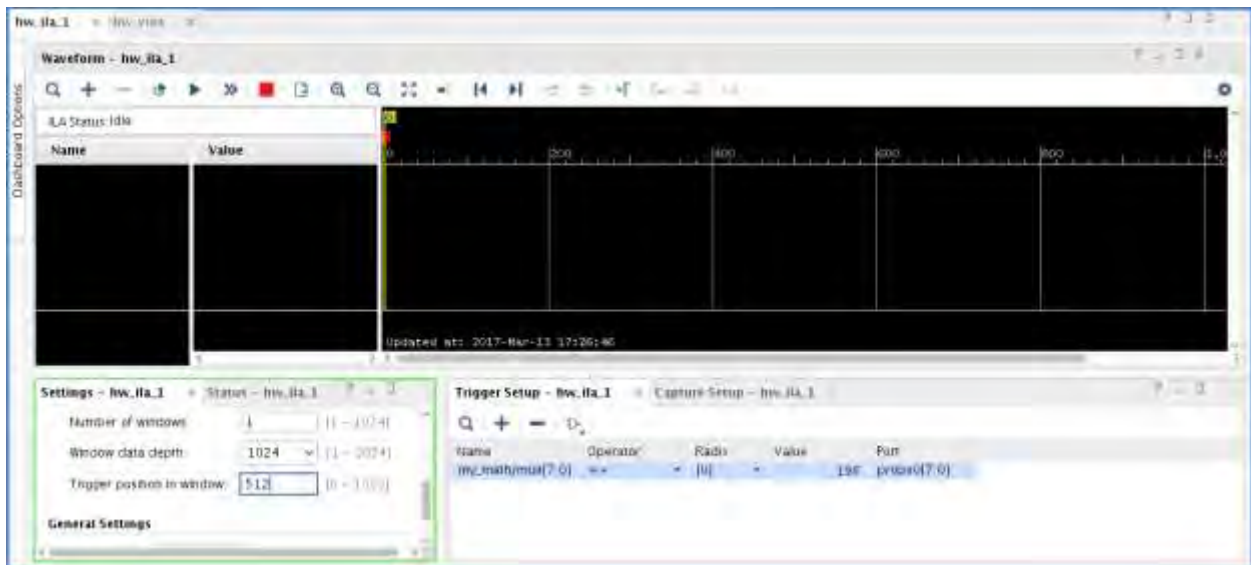

Figure 75: Setting the trigger position

15. Click on the **run trigger** button in the waveform toolbar. You will see the transition of the waveform from 169 to 196 (i.e. 13^2 to 14^2).

Note: Make sure the VIO does not have the design paused, or the trigger will not occur.

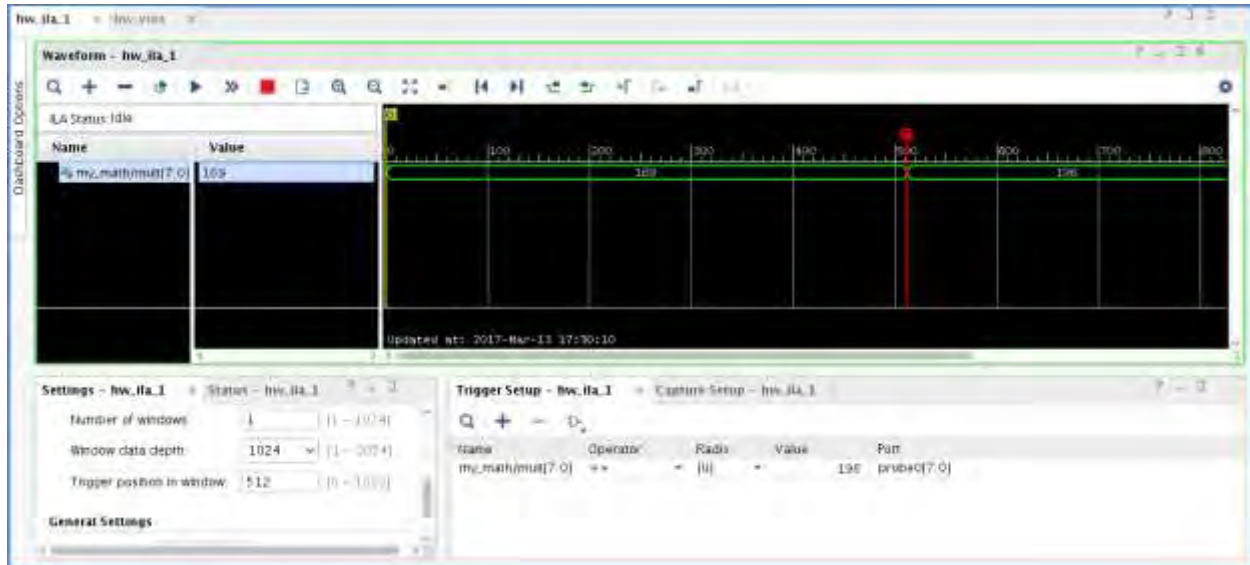

Figure 76: Watching the multiply function

16. Now load the partial bitstream for the adder. Right click on the target part in the hardware view and choose **Program Device**.
17. If you are targeting an UltraScale part, you must first program the clearing bitstream to prepare the design for the next partial bitstream. For the bitstream file choose the multiplier clearing bitstream. Navigate to the `project_1.runs/impl1/` directory and choose the **my_math_mult_partial_clear.bit** file.

Figure 77: Selecting the clearing bitstream that corresponds to the current RM

The paired LTX file will be picked up automatically. Click **Program**.

18. Switch to the VIO dashboard, and observe that the counter is still counting. If you press the toggle button to switch to the multiplier output, the value is held at 255. This is because the logic in the Reconfigurable Partition is currently disabled. Click the toggle button to switch back to the counter. Remember, `vio_select` must be set to a 1 to control remotely.
19. Right click on the target part in the hardware view and choose **Program Device...**

20. For the Bitstream file, navigate to the `project_1.runs/child_0_impl_1/` directory and choose the **my_math_add_partial.bit** file.

Figure 78: Selecting the new partial bitstream

Once again, the matching LTX file will populate automatically. Click **Program**.

21. On the VIO dashboard. Select **pause**. In this case, the value stopped at 6. After a toggle, the value is 18. The adder adds the same number 3 times.

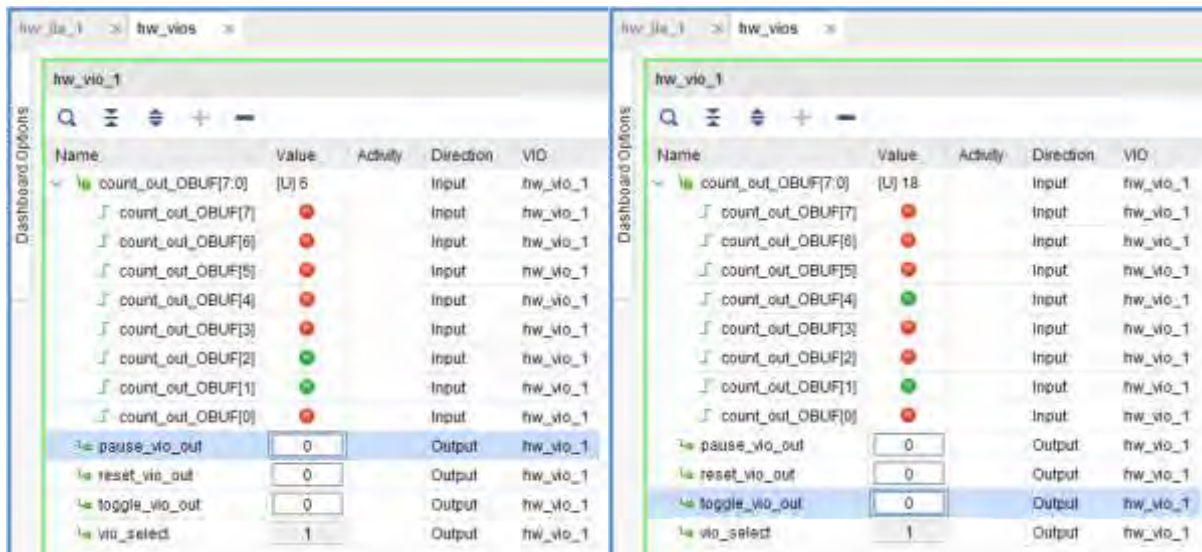

Figure 79: The add function in action

22. Switch to the ILA dashboard. In the trigger setup window click **+** and add **my_math/outtemp2[5:0]** bus. Change the following settings for the trigger:

- Radix = unsigned decimal
- Value = 30

23. In the ILA settings window change the trigger position to 512.

24. In the waveform window, click the **+** button and add the **my_math/outtemp2[5:0]** bus to the waveform. Right-click on the probe and change the radix to unsigned decimal.

25. In the waveform window, click the trigger button for the ILA. You will see the transition from 27 (9+9+9) to 30 (10+10+10).

Note: Make sure the VIO does not have the design paused.

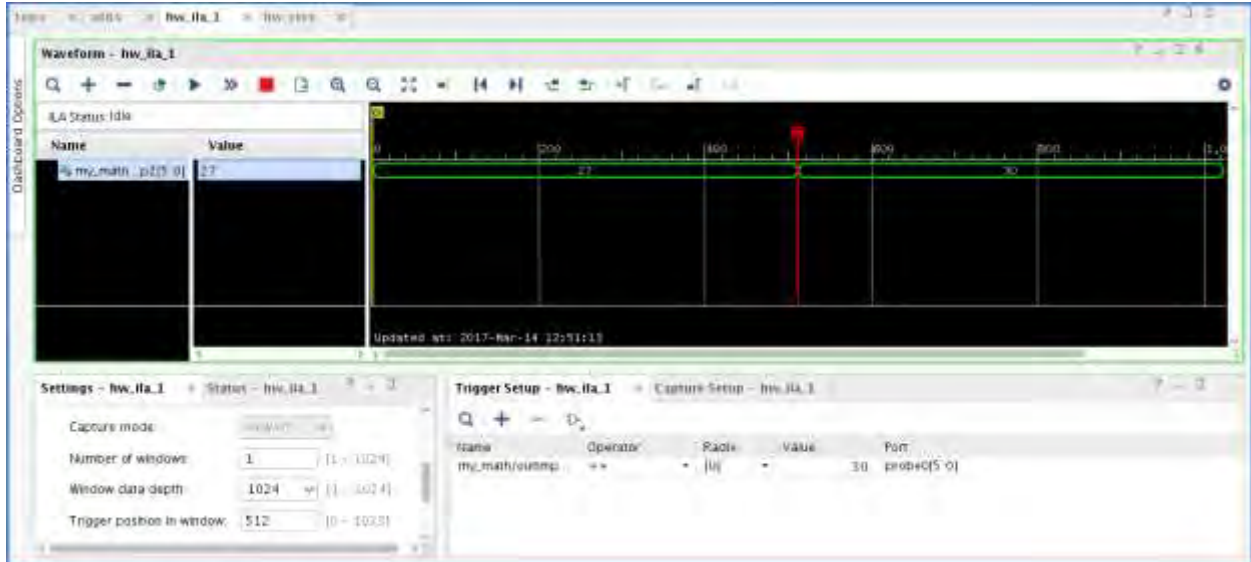

Figure 80: Watching the add function

Close the Hardware Manager when you are satisfied that everything is functioning properly.

Conclusion

With the addition of RM-level debug, any part of a Partial Reconfiguration design is debuggable. Users can easily switch between different RMs within the Hardware Manager to monitor design activity just as you would in a flat design.

Lab 5: Partial Reconfiguration Controller IP for 7 Series Devices

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see Tutorial Design Description.
 2. Navigate to `\prc_7s` in the extracted files. The `prc_7s` data directory is referred to throughout the lab as the `<Extract_Dir>`.
-

Step 2: Customizing the Partial Reconfiguration Controller IP

The PRC IP requires a few details to be entered during the customization process. Identifying all information regarding each Reconfigurable Partition (RP) and Reconfigurable Module (RM) creates a fully populated controller that understands the entirety of the reconfiguration needs of the target FPGA. Within this IP, reconfigurable portions of the design are referred to as Virtual Sockets, which encompasses the RP along with all associated static logic used to manage it, such as decoupling or handshaking logic. While the core parameters are customizable during operation, the more that can be entered during this step, the better. This allows the front-end design description to more accurately match the final implemented design.

1. Open the Vivado IDE and click the **Manage IP** task, and select **New IP Location**. Enter the following details before clicking **Finish**:
 - Part: Click on **Boards** to select your target. This lab supports the KC705, VC707 and VC709.
 - IP Location: `<Extract_Dir>/Sources/ip`
2. In the **IP Catalog**, expand the Partial Reconfiguration category to double-click on the Partial Reconfiguration Controller IP.

Partial Reconfiguration Controller		Production	Included	xilinx.com:ip:prc:1.3
Partial Reconfiguration Decoupler		Production	Included	xilinx.com:ip:pr_decoupler:1.0
PR AXI Shutdown Manager	AXI4	Production	Included	xilinx.com:ip:pr_axi_shutdown_manager:1.0
PR Bitstream Monitor	AXI4	Production	Included	xilinx.com:ip:pr_bitstream_monitor:1.0

Figure 81: The Partial Reconfiguration Controller as shown in the IP Catalog

The PR Controller IP GUI has four tabs on the left side, providing feedback on the current configuration of the IP. The default pane is labeled Validation, and shows any errors that might arise as the core parameters are entered. The core does not compile if errors exist.

There are two tabs on the right side of the GUI where all customization is done. Most of the information is entered on the **Virtual Socket Manager Options** tab.

3. Leave the component name as **prc_0**. The version of the PRC used in the final design will be automatically compiled in Step 3: Compiling the Design.
4. On the Global Options tab, make three changes:
 - a. **Set the polarity of reset and icap_reset = 1**
 - b. **Specify the CAP arbitration protocol = 1) Latency has not been added to arbiter signals**
 - c. **Specify the number of Clock domain crossing stages = 2**

Make sure that the **Managed device type** is set to 7 Series. The PRC GUI should now look like this:

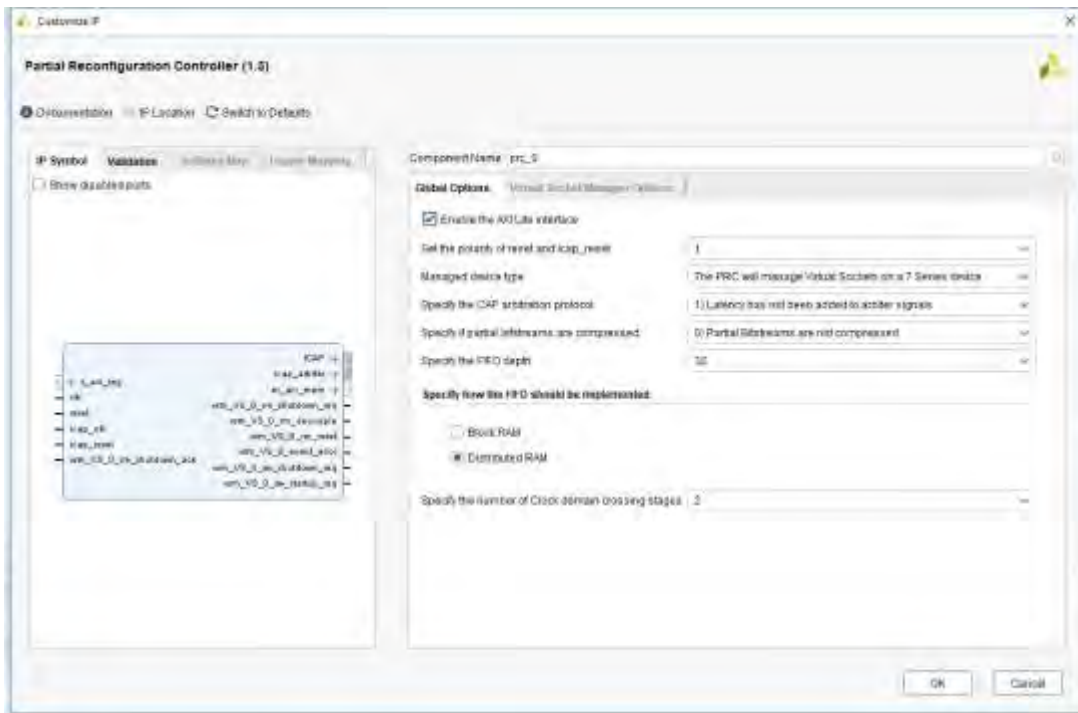

Figure 82: Component Name and Global Options completed

Note that this PR Controller can manage Virtual Sockets on 7 series, UltraScale, UltraScale+ devices. This IP is not limited to managing PR on the same device on which it resides. It can connect to an ICAP on another device to manage its reconfiguration.

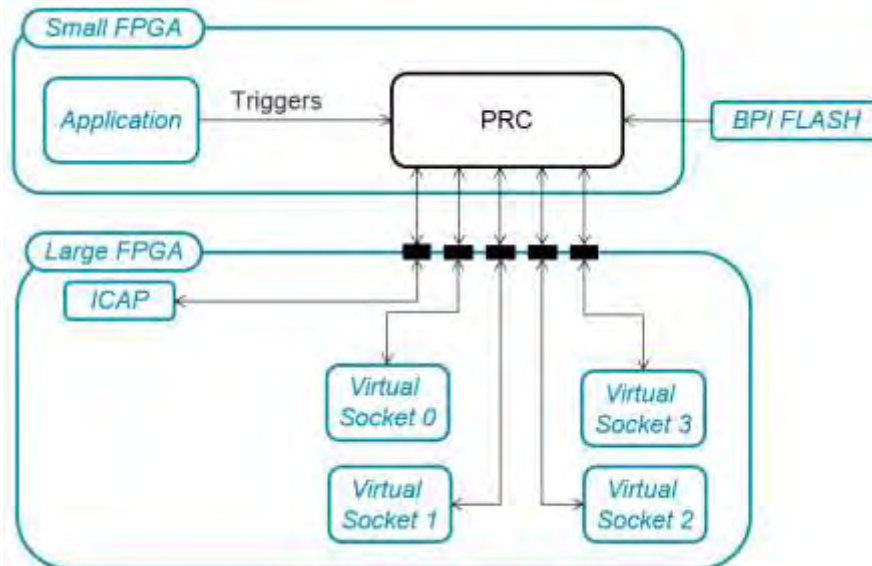

Figure 83: Example of a multi-chip solution using the PRC

- Next, switch to the **Virtual Socket Manager Options** tab to define information about the Virtual Sockets and their Reconfigurable Modules.

The PRC IP is preloaded with one Virtual Socket with one Reconfigurable Module to get you started.

First, define the Virtual Socket Manager (VSM) for the Shift functionality.

- Rename the current VSM from **VS_0** to **vs_shift** in the **Virtual Socket Name** field.
- Rename the current RM from **RM_0** to **rm_shift_left** in the **Reconfigurable Module Name** field.

CAUTION!

- Underscores are not visible in the Virtual Socket Manager and Reconfigurable Module pull-down dialogs. The **Name** (ID) label below the pull-down shows this more accurately.
- To accept a new value in any field in the GUI, simply click in any other field in the GUI or press the Tab key. Do NOT press Enter, as this will trigger compilation of the IP.

- Click the **New Reconfigurable Module** button to create a new RM for this VSM. Notice the form has changed. The new, generic, Reconfigurable Module Name is **RM_1**. Name it **rm_shift_right**.

TIP: Up to 128 Reconfigurable Modules can be managed by a single Virtual Socket Manager.

9. Configure the vs_shift VSM to have the following properties:

- **Has Status Channel = checked**
- **Has PoR RM = rm_shift_right**
- **Number of RMs allocated = 4**

The PoR RM indicates which RM is contained within the initial full-design configuration file, so the VSM knows which triggers and events are appropriate upon startup of the FPGA. The VSM tracks the current active Reconfigurable Module in its socket.

Even though you have only defined two RMs for this Virtual Socket, you have set aside space for four in total. This allows for expansion later on. Additional Reconfigurable Modules can be identified using the AXI4-Lite interface, but only if spaces have been reserved for them.

10. For each of these RMs, enter the following values. Use the **Reconfigurable Module to configure** pull-down to switch between the two RMs.

- For `rm_shift_left`:
 - **Reset type = Active High**
 - **Duration of Reset = 3**
- For `rm_shift_right`:
 - **Reset type = Active High**
 - **Duration of Reset = 10**

***Note:** The different reset durations are given to show that these can be independently assigned, as each RM may have different requirements. Reset durations are measured in clock cycles.*

11. For each RM, assign a bitstream size and location to identify where it will reside in the BPI flash device. These values differ based on the target board.

- When targeting the KC705:
 - For `rm_shift_left`:
 - **Bitstream 0 address = 0x00AEA000**
 - **Bitstream 0 size (bytes) = 482828**
 - For `rm_shift_right`:
 - **Bitstream 0 address = 0x00B60000**
 - **Bitstream 0 size (bytes) = 482828**

- When targeting the VC707:
 - For `rm_shift_left`:
 - **Bitstream 0 address = 0x01355C00**
 - **Bitstream 0 size (bytes) = 708260**
 - For `rm_shift_right`:
 - **Bitstream 0 address = 0x01402C00**
 - **Bitstream 0 size (bytes) = 708260**
- When targeting the VC709:
 - For `rm_shift_left`:
 - **Bitstream 0 address = 0x00800000**
 - **Bitstream 0 size (bytes) = 889252**
 - For `rm_shift_right`:
 - **Bitstream 0 address = 0x008D9400**
 - **Bitstream 0 size (bytes) = 889252**

This information is typically not known early in design cycles, as bitstream size is based on the size and composition of the Reconfigurable Partition Pblock, and bitstream address is based on storage details. Until the design is to be tested on silicon, these can be set to 0. As the design settles and hardware testing with the PRC is set to begin, this information can be added. The bitstream address information must match the information passed during PROM file generation. Certain bitstream generation options, most notably bitstream compression, can lead to variations in the final bitstream size for different configurations, even for the same Reconfigurable Partition.

12. Define the **Trigger Options** for the Shift functionality:

- **Number of Hardware Triggers = 4**
- **Number of Triggers allocated = 4**

The four trigger assignments are done automatically. These can be modified during device operation using AXI4-Lite, which is especially useful when you have added a new RM through the same mechanism during a field system upgrade.

At this point, the IP GUI should look like this (showing `rm_shift_left` here):

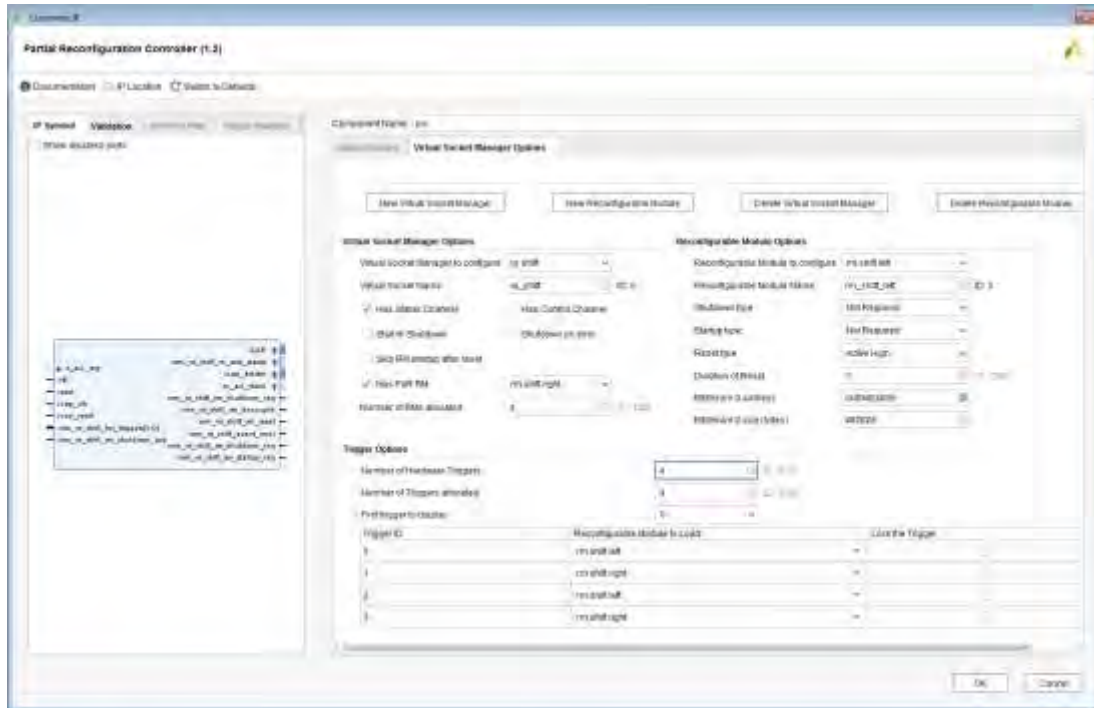

Figure 84: VSM vs_shift completed

Next, you will create and populate the Count Virtual Socket following the same basic steps, with slightly different options.

13. Click the **New Virtual Socket Manager** button to create a new VSM.
14. Select the **New Reconfigurable Module** button to add two RMs with these names and properties:
 - RM Name = `rm_count_up`
 - Reset type = **Active High**
 - Duration of Reset = **12**
 - RM Name = `rm_count_down`
 - Reset type = **Active High**
 - Duration of Reset = **16**

For this Virtual Socket, leave the bitstream address and size information at the default of 0. In addition to being defined here, bitstream size information can be added to a routed configuration checkpoint via the PRC Tcl API, or can be added in an active design using the AXI4-Lite interface. For the Count Virtual Socket, the bitstream address and size information is added using the Tcl commands after place and route, but before bitstream generation.

TIP: For more information about how to use the PRC Tcl API, see this [link](#) in the Partial Reconfiguration Controller Product Guide (PG193).

Examine the Tcl scripts in the `<Extract_Dir>/Sources/scripts` directory. The `update_prc_<board>.tcl` uses the PRC Tcl API to update the bitstream address and bitstream size, which is stored in `pr_info_<board>.tcl`. This file is sourced later in the lab from `<Extract_Dir>/design.tcl`.

15. On the VSM tab, modify these VSM settings from their default values:
 - o Virtual Socket Manager name = **vs_count**
 - o Start in Shutdown = **checked**
 - o Shutdown on error = **unchecked**
 - o Has PoR RM = **checked, rm_count_up**
16. Define the Trigger Options for the Count functionality:
 - o Number of Hardware Triggers = **4**
 - o Number of Triggers allocated = **4**

This completes the planned customization of the PRC IP for this tutorial.

17. Click **OK** and then **Generate** to begin core compilation and out-of-context synthesis.

Figure 85: Final PRC symbol

Step 3: Compiling the Design

The PR Controller IP is created, but the design is not yet compiled. In order to create the PROM image with all the necessary full and partial images, source the following scripts in Tcl mode using the commands below.

IMPORTANT: Before running this Tcl script, open it to set the value of the `xboard` variable. `KC705` is the default, but `VC707` or `VC709` can be selected.

1. `vivado -mode tcl -source design.tcl`

Sourcing `design.tcl` generates all the necessary IP (including the PRC), synthesizes and implements the entire design (three configurations), updates the `vs_count` VSM using the PRC Tcl API, and generates bitstreams.

Note that the customization of the IP is scripted. Examine the `gen_ip_<board>.tcl` script (in `<Extract_Dir>/Sources/scripts`) to see all these parameters defined for automated IP creation, the PRC, and others. The PRC instance you create using the IP GUI is not actually used for the full design processing, so you do not have to complete Section 1 to compile the entire design.

2. `vivado -mode tcl -source create_prom_file_<board>.tcl`

Sourcing the board-specific `create_prom_file.tcl` creates the PROM image for the target board. This script contains hard-coded values for bitstream address for the entire project. If this design is modified in such a way that changes bitstream sizes, full or partial, then these values must also change. Changes that affect bitstream sizes include changing the target device, changing the size or shape of the Pblocks, or introducing bitstream options such as compression or per-frame CRC.

This script defines PROM file options by setting properties and then making calls to `write_cfgmem`. The PRC works in byte addresses because the data is stored in bytes in AXI. This linear flash PROM uses half word addresses because it stores data in half words (16 bits). Divide the ROM address by 2 to get the AXI address. For example, the `shift_left` address for the `KC705` is given as `00AEA000` in during PRC customization and `00575000` (half that value) for `write_cfgmem`. Note that the starting addresses are always multiples of 1024 (`0x0400`) to ensure that each bitstream starts on a byte address boundary. Also note that the initial configuration file for the `VC709` is compressed in order to fit in the linear flash; the address for the first partial bitstream that follows is padded to allow expansion of that initial configuration file.

Supplied in the lab directory is a file called `prc_bitstream_sizes_lab5.xlsx`. In this file, bitstream sizes are entered by the user based in the yellow highlighted fields. It calculates the starting address in hex for each partial bitstream at the next byte boundary. Values in blue are to be supplied for PR Controller IP customization, in either the PRC IP GUI, in the `gen_ip_<board>.tcl` script, or in `pr_info_<board>.tcl` which is used for post-route API modification. The values in green are addresses divided by two to be used in PROM file generation in the `create_prom_file_<board>.tcl` script.

Step 4: Setting up the Board

Once the partially reconfigurable design is in operation, you can connect to and communicate with the core to check status, deliver triggers and make modifications.

1. Prepare the target board for programming.
 - a. Connect the JTAG port to your computer via the micro-USB connection.
 - For the KC705: U59
 - For the VC707 or VC709: U26
 - b. Set the configuration mode to 010 (BPI) by setting the Address DIP Switch (SW13) to 00010 (bit 4 is high).
 - c. Turn on the power to the board.
2. Open the Vivado IDE.
3. Select **Flow > Open Hardware Manager**
4. Click on the **Open Target** link and select **Auto Connect** for the device to be recognized.
5. To program the BPI configuration flash, right-click the device (e.g. **xc7k325t_0**) and select **Add Configuration Memory Device**.
6. From the list shown, select the appropriate linear BPI flash and click **OK** twice.
 - For the KC705, select **28f00ap30t**
 - For the VC707 or VC709, select **28f00ag18f**
7. In the **Configuration file** field, search the tutorial directory for `pr_prom.mcs` found in the bitstreams subdirectory. Click **OK** to select this file, and then click **OK** to program the flash.

At this point, the board is ready to operate with the tutorial design. Any power-cycle or hard reset automatically programs the Xilinx FPGA with this sample design.

Step 5: Operating the Sample Design

Position the board so that the text is readable. The LCD screen is on the side closest to you, with the power connection on the right and the JTAG connection on the left. The buttons of interest are the five user push buttons in the lower right corner, plus the **PROG** push button in the middle right.

Their functions for the KC105 are as follows:

- PROG (SW14) – program the device from the BPI flash
- North (SW2) – load the Count Up partial bit file
- South (SW4) – load the Count Down partial bit file
- East (SW3) – load the Shift Right partial bit file
- West (SW6) – load the Shift Left partial bit file
- Center (SW5) – reset the design

Figure 86: Push buttons, switches and connections on the KC705 demonstration board

Their functions for the VC707 and VC709 are as follows:

- PROG (SW9) – program the device from the BPI flash
- North (SW3) – load the Count Up partial bit file
- South (SW5) – load the Count Down partial bit file
- East (SW4) – load the Shift Right partial bit file
- West (SW7) – load the Shift Left partial bit file
- Center (SW6) – reset the design

Figure 87: Push buttons, switches and connections on the VC707 demonstration board

Figure 88: Push buttons, switches and connections on the VC709 demonstration board

8. Program the FPGA by pressing the **PROG** pushbutton. The 8 GPIO LEDs in the upper-right corner will start operation after the DONE LED goes high.
At this point, the four bits on the left of the GPIO bank are counting up, and the four bits on the right are shifting to the right.
9. Press the **Shift Left** and **Shift Right** buttons alternately.
With each push, a partial bit file is pulled from the BPI flash by the PRC and delivered to the ICAP, changing the functionality in that Reconfigurable Partition. When this happens, the LED shift direction changes, depending on the button pushed.
10. Press the **Count Down** and **Count Up** buttons alternately.
With each push, nothing happens. When configuring the PR Controller, the Counter Virtual Socket was programmed to begin in Shutdown mode. It does not respond to any hardware or software triggers until it is moved to Active mode.

Step 6: Querying the PRC in the FPGA

In this step, you interact with the core via JTAG from the Hardware Manager to understand the status of the core and issue software triggers.

In the Vivado Hardware Manager, you might need to select **Refresh Device** to establish the link to the device over the JTAG connection. Notice the XADC as well as 6 ILA cores and the `hw_axi` link shown under the device in the Hardware view.

1. In the Tcl Console, cd into the PRC tutorial directory then source the AXI4-Lite command Tcl script.

```
source ./Sources/scripts/axi_lite_procs.tcl
```

This enables a set of procedures that make the subsequent interaction with the PRC easier. Examine this file to see how these procedures are defined. Note that these are written explicitly (hard-coded) for this design, the references to Virtual Sockets in any other design will need to be modified. For more information on this topic, consult the *Partial Reconfiguration Controller Product Guide* (PG193).

2. Source the procedure to establish communication with the PRC.

```
prc_jtag_setup
```

3. Check the state of each Virtual Socket to see if they are in Shutdown or not.

```
is_vsm_in_shutdown vs_shift
is_vsm_in_shutdown vs_count
```

You should see that the Shift Virtual Socket is in Active mode (value = 0), and the Count Virtual Socket is in Shutdown mode (value = 1).

4. Examine the status of each Virtual Socket.

```
prc_decode_status vs_shift
prc_decode_status vs_count
```

Before examining the data returned, reference Table 2-4 in this [link](#) of the *Partial Reconfiguration Controller Product Guide* (PG193). The table in that section defines the values in the STATUS register. While this is a 32-bit register, you only need to pay attention to the lowest 24 bits, as the upper 8 bits are used for Virtual Socket Managers (VSM) in UltraScale devices.

The status of `vs_shift` is 263, which is 0000_0000_0000_0001_0000_0111 in binary. The status for `vs_shift` may also be 7, where the only difference is that `RM_ID` is now 0.

- `RM_ID` (bits 23:8) = 1. This means RM 1 is loaded (`rm_shift_right`). It may also appear as `RM_ID` (bits 24:8) = 0. This means RM 0 is loaded (`rm_shift_left`).
- `SHUTDOWN` (bit 7) = 0. This VSM is not in the shutdown state.
- `ERROR` (bits 6:3) = 0000. There are no errors.
- `STATE` (bits 2:0) = 111. The Virtual Socket is full.

The status of `vs_count` is 129, which is 0000_0000_0000_0000_1000_0001 in binary.

- `RM_ID` (bits 23:8) = 0. This means RM 0 is loaded (`rm_count_up`).
- `SHUTDOWN` (bit 7) = 1. This VSM is in the shutdown state.
- `ERROR` (bits 6:3) = 0000. There are no errors.
- `STATE` (bits 2:0) = 001. `RM_SHUTDOWN_ACK` is 1, as this VSM is executing the hardware shutdown step.

These explicit details are reported in the breakdown of the status register in the return value from this Tcl proc.

5. Send a software trigger to the Shift Virtual Socket.

```
prc_send_sw_trigger vs_shift 0
prc_send_sw_trigger vs_shift 1
```

Remember that values of 0 and 2 correspond to shift left, and values of 1 and 3 correspond to shift right, as defined during PRC customization.

6. Check the configurations of the RMs for the Count Virtual Socket.

```
prc_show_rm_configuration vs_count 0
prc_show_rm_configuration vs_count 1
```

The values for the bitstream sizes and address are reported here. These values could then be modified to account for necessary adjustments to the size or location of the bitstream. Different indices can be added to insert new RMs. Note that this query cannot be done for `vs_shift`, as the `vs_shift` VSM is not in the shutdown state.

7. Move the Count Virtual Socket Manager into active mode.

```
prc_restart_vsm_no_status vs_count
```

The Count Up and Count Down pushbuttons can now be used to load these partial bitstreams using the PR Controller.

Step 7: Modifying the PRC in the FPGA

In the final step, you add a new Reconfigurable Module to the Shifter VSM. In the `create_prom_file_<board>.tcl` script, you can see that two black box modules have already been generated. These represent two new RMs that may have been created after the static design was deployed to the field. You modify the PRC settings to access one of these RMs by assigning the size, address, properties and trigger conditions.

1. Shut down the Shift VSM so it can be modified.

```
prc_shutdown_vsm vs_shift
```

2. Check the status of the first three RM IDs to see their register bank assignments.

```
prc_show_rm_configuration vs_shift 0
prc_show_rm_configuration vs_shift 1
prc_show_rm_configuration vs_shift 2
```

Currently, RM ID 2 has the same mapping as RM ID 0, so the same shift left partial bitstream would be loaded. This is the behavior as requested when the initial trigger mapping was done during core customization.

3. When the MCS file is created for the prom, it adds additional blanking RMs that are already loaded into the BPI flash. Use this sequence of commands to reassign the trigger mapping for slot 2 to point to the blanking Reconfigurable Module for `vs_shift`.

```
prc_write_register vs_shift_rm_control2 0
```

This defines the settings for the `RM_CONTROL` register for slot 2. No shutdown, startup, or reset are required. Note how for the other two slots, the differing reset durations lead to different control values.

```
prc_write_register vs_shift_rm_bs_index2 2
```

This assigns a new bitstream reference for this RM ID.

```
prc_write_register vs_shift_trigger2 2
```

This assigns the trigger mapping such that trigger index 2 retrieves RM 2.

```
prc_show_rm_configuration vs_shift 2
```

This shows the current state of RM ID 2. Note the changes from the prior call to this command.

4. Complete the RM ID 2 customization by setting the bitstream details.

For the KC705:

```
prc_write_register vs_shift_bs_size2 482828
prc_write_register vs_shift_bs_address2 13496320
```

For the VC707:

```
prc_write_register vs_shift_bs_size2 708260
prc_write_register vs_shift_bs_address2 23108608
```

For the VC709:

```
prc_write_register vs_shift_bs_size2 889252
prc_write_register vs_shift_bs_address2 11960320
```

5. Restart the VSM and then issue trigger events to it using software, as there is no pushbutton assigned for slot 2.

```
prc_restart_vsm_no_status vs_shift
prc_send_sw_trigger vs_shift 2
```

Switch between values of 0, 1 and 2 to reload different partial bitstreams.

Note that this same sequence of events could not be performed for the Count VSM as it is currently configured, even knowing that the PROM image has a Count black box partial bitstream sitting at (for the KC705) address 13979648 with a size of 541812. During PRC customization, this VSM was selected to have only 2 RMs allocated, so expansion is not permitted.

Conclusion

This concludes lab 5. In this lab, you:

- Customized the Partial Reconfiguration Controller IP.
- Created a Virtual Sockets and added RMs to them.
- Compiled the design and created a PROM file.
- Programmed the linear flash on the KC705, VC707 or VC709 board.
- Used pushbuttons to issue hardware triggers.
- Used the AXI-Lite interface to check the core status and issue software triggers.
- Added a new RM to an already deployed design.

Lab 6: Partial Reconfiguration Controller IP for UltraScale Devices

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see Tutorial Design Description.
2. Navigate to \prc_us in the extracted files. The prc_us data directory is referred to throughout the lab as the <Extract_Dir>.

Step 2: Customizing the Partial Reconfiguration Controller IP

The PRC IP requires a few details to be entered during the customization process. Identifying all information regarding each Reconfigurable Partition (RP) and Reconfigurable Module (RM) creates a fully populated controller that understands the entirety of the reconfiguration needs of the target FPGA. Within this IP, reconfigurable portions of the design are referred to as Virtual Sockets, which encompasses the RP along with all associated static logic used to manage it, such as decoupling or handshaking logic. While the core parameters are customizable during operation, the more that can be entered during this step, the better. This allows the front-end design description to more accurately match the final implemented design.

1. Open the Vivado IDE and click the **Manage IP** task, and select **New IP Location**. Enter the following details before clicking **Finish**:
 - Part: Click on **Boards** to select the **VCU108**
 - IP Location: <Extract_Dir>/Sources/ip

NOTE: The KCU105 development board is not supported, as the boot flash on this board is a QSPI device. QSPI and sync-mode BPI configuration schemes are not supported for Partial Reconfiguration. See Table 8-1 in this [link](#) of Vivado Design Suite User Guide: Partial Reconfiguration (UG909).
2. In the **IP Catalog**, expand the Partial Reconfiguration category to double-click on the Partial Reconfiguration Controller IP.

Partial Reconfiguration			
Partial Reconfiguration Controller	Production	Included	xilinx.com:ip:prc:1.2
Partial Reconfiguration Decoupler	Production	Included	xilinx.com:ip:pr_decoupler:1.0

Figure 89: The Partial Reconfiguration Controller as shown in the IP Catalog

The PR Controller IP GUI has four tabs on the left side, providing feedback on the current configuration of the IP. The default pane is labeled Validation, and shows any errors that might arise as the core parameters are entered. The core does not compile if errors exist.

There are two tabs on the right side of the GUI where all customization is done. Most of the information is entered on the **Virtual Socket Manager Options** tab.

3. Leave the component name as **prc_0**. The version of the PRC used in the final design will be automatically compiled in Step 3: Compiling the Design.
4. On the Global Options tab, make three changes:
 - a. Set the Polarity of reset and icap_reset = **1**
 - b. Specify the CAP arbitration protocol = **1) Latency has not been added to arbiter signals**
 - c. Set the number of Clock domain crossing stages = **2**

Make sure that the **Managed device type** is set to UltraScale. The PRC GUI should now look like this:

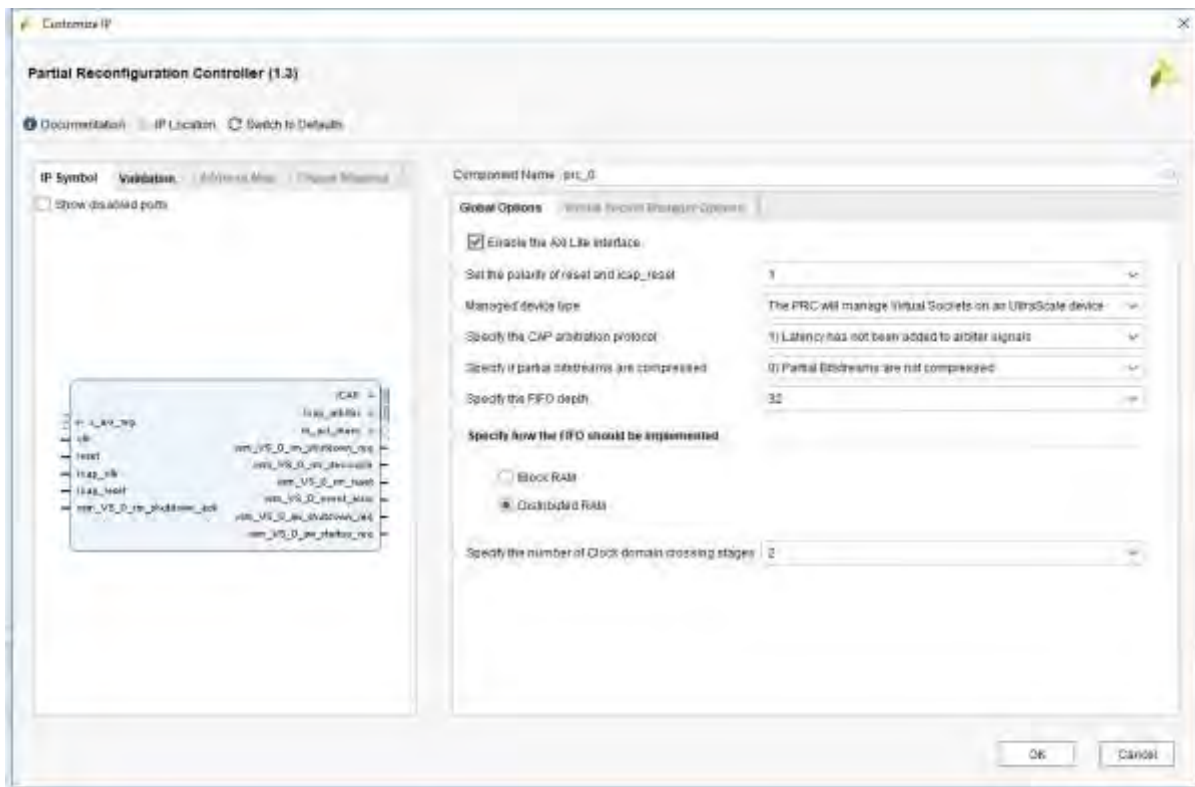

Figure 90: Component Name and Global Options completed

Note that this PR Controller can manage Virtual Sockets on 7 series, UltraScale, or UltraScale+ devices. This IP is not limited to managing PR on the same device on which it resides. It can connect to an ICAP on another device to manage its reconfiguration.

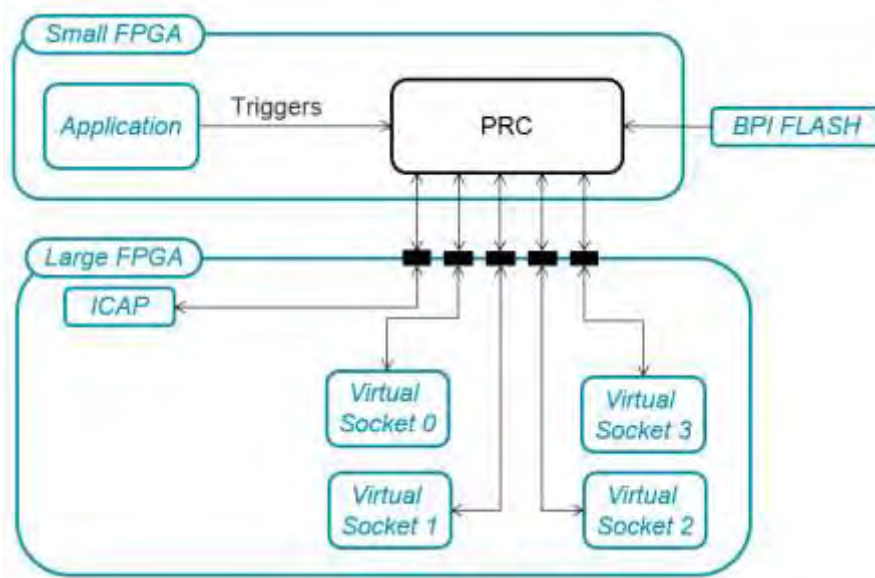

Figure 91: Example of a multi-chip solution using the PRC

- Next, switch to the **Virtual Socket Manager Options** tab to define information about the Virtual Sockets and their Reconfigurable Modules.

The PRC IP is preloaded with one Virtual Socket with one Reconfigurable Module to get you started.

First, define the Virtual Socket Manager (VSM) for the Shift functionality.

- Rename the current VSM from **VS_0** to **vs_shift**.
- Rename the current RM from **RM_0** to **rm_shift_left**.

CAUTION!

- Underscores are not visible in the Virtual Socket Manager and Reconfigurable Module pull-down dialogs. The **Name** (ID) label below the pull-down shows this more accurately.
- To accept a new value in any field in the GUI, simply click in any other field in the GUI or press the Tab key. Do NOT press Enter, as this will trigger compilation of the IP.

- Click the **New Reconfigurable Module** button to create a new RM for this VSM. Name it **rm_shift_right** in the **Reconfigurable Module Name** field.

TIP: Up to 128 Reconfigurable Modules can be managed by a single Virtual Socket Manager.

9. Configure the vs_shift VSM to have the following properties:

- Has Status Channel = **checked**
- Has PoR RM = **rm_shift_right**
- Number of RMs allocated = **4**

The PoR RM indicates which RM is contained within the initial full-design configuration file, so the VSM knows which triggers and events are appropriate upon startup of the FPGA. The VSM tracks the current active Reconfigurable Module in its socket.

Even though you have only defined two RMs for this Virtual Socket, you have set aside space for four in total. This allows for expansion later on. Additional Reconfigurable Modules can be identified using the AXI4-Lite interface, but only if spaces have been reserved for them.

10. For each of these RMs, enter the following values. Use the **Reconfigurable Module to configure** pull-down to switch between the two RMs.

- For `rm_shift_left`:
 - Reset type = **Active High**
 - Duration of Reset = **3**
- For `rm_shift_right`:
 - Reset type = **Active High**
 - Duration of Reset = **10**

***Note:** The different reset durations are given to show that these can be independently assigned, as each RM may have different requirements. Reset durations are measured in clock cycles.*

11. For each RM, assign a bitstream size and location to identify where it will reside in the BPI flash device.

- For `rm_shift_left`:
 - Bitstream 0 address = **0x00B00000**
 - Bitstream 0 size (bytes) = **375996**
 - Bitstream 0 is a clearing bitstream = **unchecked**
 - Bitstream 1 address = **0x00B5C000**
 - Bitstream 1 size (bytes) = **26036**
 - Bitstream 1 is a clearing bitstream = **checked**

- For `rm_shift_right`:
 - Bitstream 0 address = **0x00B62800**
 - Bitstream 0 size (bytes) = **375996**
 - Bitstream 0 is a clearing bitstream = **unchecked**
 - Bitstream 1 address = **0x00BBE800**
 - Bitstream 1 size (bytes) = **26036**
 - Bitstream 1 is a clearing bitstream = **checked**

This information is typically not known early in design cycles, as bitstream size is based on the size and composition of the Reconfigurable Partition Pblock, and bitstream address is based on storage details. Until the design is to be tested on silicon, these can be set to 0. As the design settles and hardware testing with the PRC is set to begin, this information can be added. The bitstream address information must match the information passed during PROM file generation. Certain bitstream generation options, most notably bitstream compression, can lead to variations in the final bitstream size for different configurations, even for the same Reconfigurable Partition.

12. Define the Trigger Options for the Shift functionality:

- Number of Hardware Triggers = **4**
- Number of Triggers allocated = **4**

The four trigger assignments are done automatically. These can be modified during device operation using AXI4-Lite, which is especially useful when you have added a new RM through the same mechanism during a field system upgrade.

At this point, the IP GUI should look like this (showing `rm_shift_left` here):

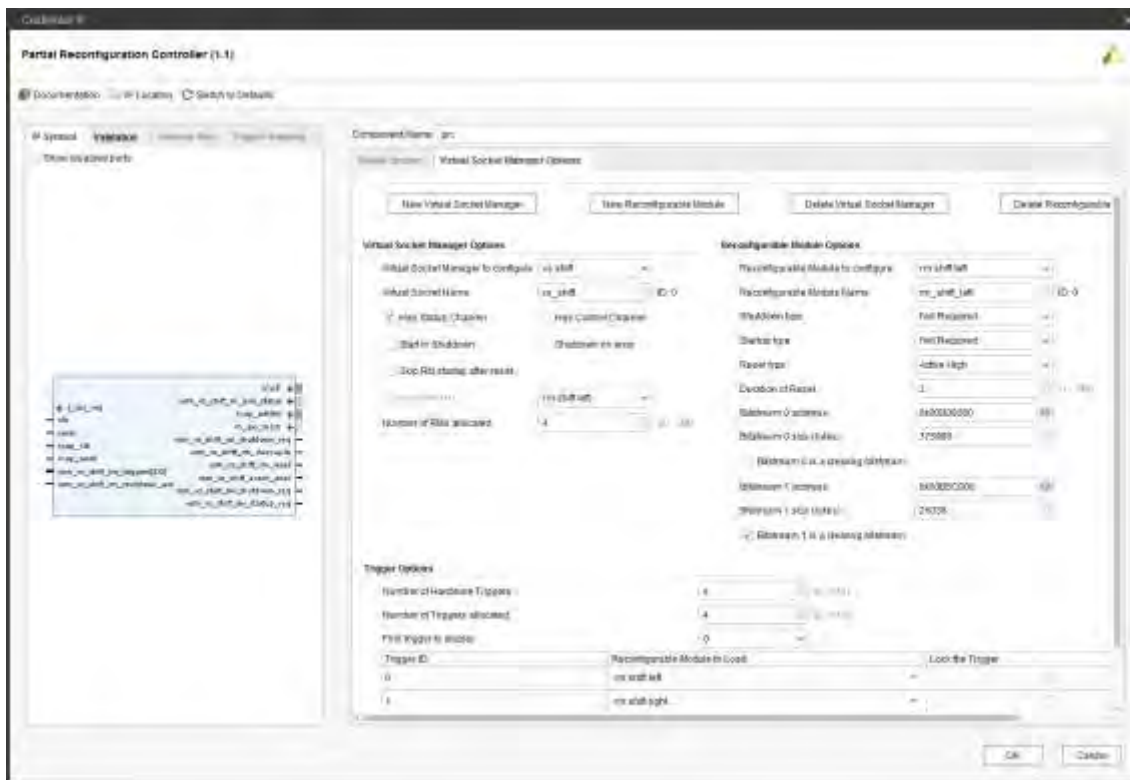

Figure 92: VSM vs_shift completed

Next, you will create and populate the Count Virtual Socket following the same basic steps, with slightly different options here and there.

13. Click the **New Virtual Socket Manager** button to create a new VSM.

14. Add two RMs with these names and properties:

- RM Name = `rm_count_up`
 - Reset type = **Active High**
 - Duration of Reset = **12**
- RM Name = `rm_count_down`
 - Reset type = **Active High**
 - Duration of Reset = **16**

For this Virtual Socket, leave the bitstream address and size information at the default of 0, but set bitstream 1 to be a clearing bitstream. In addition to being defined here, bitstream size information can be added to a routed configuration checkpoint via the PRC Tcl API, or can be added in an active design using the AXI4-Lite interface. For the Count Virtual Socket, the bitstream address and size information is added using the Tcl commands after place and route, but before bitstream generation.

TIP: For more information about how to use the PRC Tcl API, see this [link](#) in the Partial Reconfiguration Controller Product Guide (PG193).

Examine the Tcl scripts in the `<Extract_Dir>/Sources/scripts` directory. The `update_prc_vcu108.tcl` uses the PRC Tcl API to update the bitstream address and bitstream size, which is stored in `pr_info_vcu108.tcl`. This file is sourced later in the lab from `<Extract_Dir>/design.tcl`.

15. On the VSM tab, modify these VSM settings from their default values:

- Virtual Socket Manager name = **vs_count**
- Start in Shutdown = **checked**
- Shutdown on error = **unchecked**
- Has PoR RM = **checked, rm_count_up**

16. Define the Trigger Options for the Count functionality:

- Number of Hardware Triggers = **4**
- Number of Triggers allocated = **4**

This completes the planned customization of the PRC IP for this tutorial.

17. Click **OK** and then **Generate** to begin core compilation and out-of-context synthesis.

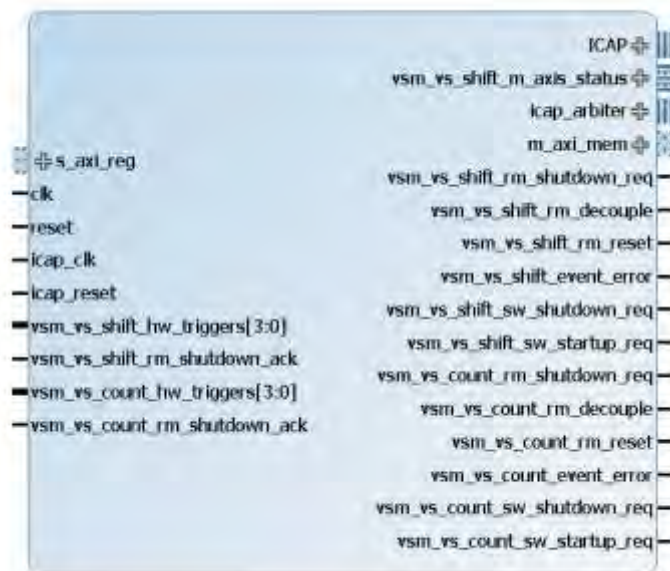

Figure 93: Final PRC symbol

Step 3: Compiling the Design

The PR Controller IP is created, but the design is not yet compiled, which could take approximately an hour. In order to create the PROM image with all the necessary full and partial images, source the following scripts in Tcl mode using the commands below.

1. `vivado -mode tcl -source design.tcl`

Sourcing `design.tcl` generates all the necessary IP (including the PRC), synthesizes and implements the entire design (three configurations), updates the `vs_count` VSM using the PRC Tcl API, and generates bitstreams.

Note that the customization of the IP is scripted. Examine the `gen_ip_vcu108.tcl` script (in `<Extract_Dir>/Sources/scripts`) to see all these parameters defined for automated IP creation, the PRC, and others. The PRC instance you create using the IP GUI is not actually used for the full design processing, so you do not have to complete Section 1 to compile the entire design.

2. `vivado -mode tcl -source create_prom_file_vcu108.tcl`

Sourcing `create_prom_file_vcu108.tcl` creates the PROM image for the VCU108 target. This script contains hard-coded values for bitstream address for the entire project. If this design is modified in such a way that changes bitstream sizes, full or partial, then these values must also change. Changes that affect bitstream sizes include changing the target device, changing the size or shape of the Pblocks, or introducing bitstream options such as compression or per-frame CRC.

This script defines PROM file options by setting properties and then making calls to `write_cfgmem`. The PRC works in byte addresses because the data is stored in bytes in AXI. This linear flash PROM uses half word addresses because it stores data in half words (16 bits). Divide the ROM address by 2 to get the AXI address. For example, the `shift_left` address is given as `00B00000` during PRC customization and `00580000` (half that value) for `write_cfgmem`. Note that the starting addresses are always multiples of 1024 (0x0400) to ensure that each bitstream starts on a byte address boundary.

Supplied in the lab directory is a file called `prc_bitstream_sizes_lab6.xlsx`. In this file, bitstream sizes are entered by the user based in the yellow highlighted fields. It calculates the starting address in hex for each partial bitstream at the next byte boundary. Values in blue are to be supplied for PR Controller IP customization, in either the PRC IP GUI, in the `gen_ip_vcu108.tcl` script, or in `pr_info_vcu108.tcl` which is used for post-route API modification. The values in green are addresses divided by two to be used in PROM file generation in the `create_prom_file_vcu108.tcl` script.

Step 4: Setting up the Board

Once the partially reconfigurable design is in operation, you can connect to and communicate with the core to check status, deliver triggers, and make modifications.

1. Prepare the VCU108 board for programming.
 - a. Connect the JTAG port (J106) to your computer via the micro-USB connection.
 - b. Set the configuration mode to 010 (BPI) by setting the Address DIP Switch (SW16) to 00010 (bit 4 is high).
 - c. Turn on the power to the board.
2. Open the Vivado IDE.
3. Select **Flow > Open Hardware Manager**
4. Click on the **Open Target** link and select **Auto Connect**. The Virtex UltraScale VU095 device will be recognized.
5. To program the BPI configuration flash, right-click the device (**xcvu095_0**) and select **Add Configuration Memory Device**.
6. From the list shown, select the Micron flash **28f00ag18f** and click **OK** twice.
7. In the **Configuration file** field, search the tutorial directory for `pr_prom.mcs` found in the bitstreams subdirectory. Click **OK** to select this file, and then click **OK** to program the flash.

At this point, the board is ready to operate with the tutorial design. Any power-cycle or hard reset automatically programs the Virtex UltraScale FPGA with this sample design.

Step 5: Operating the Sample Design

Position the board so that the text is readable. The LCD screen is on the side closest to you, with the power connection on the right and the JTAG connection on the left. The buttons of interest are the five user push buttons in the lower right corner, plus the **PROG** push button in the middle right. Their functions are as follows:

- PROG (SW4) – program the device from the BPI flash
- North (SW10) – load the Count Up partial bit file
- South (SW8) – load the Count Down partial bit file
- East (SW9) – load the Shift Right partial bit file
- West (SW6) – load the Shift Left partial bit file
- Center (SW7) – reset the design

Figure 94: Push buttons, switches and connections on the VCU108 demonstration board

1. Program the FPGA by pressing the **PROG** pushbutton. The 8 GPIO LEDs in the upper-right corner will start operation after the DONE LED goes high.
At this point, the four bits on the left of the GPIO bank are counting up, and the four bits on the right are shifting to the right.
2. Press the **Shift Left** and **Shift Right** buttons alternately.
With each push, a partial bit file is pulled from the BPI flash by the PRC and delivered to the ICAP, changing the functionality in that Reconfigurable Partition. When this happens, the LED shift direction changes, depending on the button pushed.
3. Press the **Count Down** and **Count Up** buttons alternately.
With each push, nothing happens. When configuring the PR Controller, the Counter Virtual Socket was programmed to begin in Shutdown mode. It does not respond to any hardware or software triggers until it is moved to Active mode.

Step 6: Querying the PRC in the FPGA

In this step, you interact with the core via JTAG from the Hardware Manager to understand the status of the core and issue software triggers.

In the Vivado Hardware Manager, you might need to select **Refresh Device** to establish the link to the device over the JTAG connection. Notice the XADC as well as 6 ILA cores and the `hw_axi` link shown under the device in the Hardware view.

1. In the Tcl Console, cd into the PRC tutorial directory then source the AXI4-Lite command Tcl script.

```
source ./Sources/scripts/axi_lite_procs_us.tcl
```

This enables a set of procedures that make the subsequent interaction with the PRC easier. Examine this file to see how these procedures are defined. Note that these are written explicitly (hard-coded) for this design, the references to Virtual Sockets in any other design will need to be modified. For more information on this topic, consult the *Partial Reconfiguration Controller Product Guide* (PG193).

2. Source the procedure to establish communication with the PRC.

```
prc_jtag_setup
```

3. Check the state of each Virtual Socket to see if they are in Shutdown or not.

```
is_vsm_in_shutdown vs_shift
is_vsm_in_shutdown vs_count
```

You should see that the Shift Virtual Socket is in Active mode (value = 0), and the Count Virtual Socket is in Shutdown mode (value = 1).

4. Examine the status of each Virtual Socket.

```
prc_decode_status vs_shift
prc_decode_status vs_count
```

Before examining the data returned, reference Table 2-4 in this [link](#) of the *Partial Reconfiguration Controller Product Guide* (PG193). The table in that section defines the values in the STATUS register. While this is a 32-bit register, you only need to pay attention to the lowest 24 bits, as the upper 8 bits are used for Virtual Socket Managers (VSM) in UltraScale devices.

The status of `vs_shift` is 263, which is 0000_0000_0000_0001_0000_0111 in binary. The status for `vs_shift` may also be 7, where the only difference is that `RM_ID` is now 0.

- `RM_ID` (bits 23:8) = 1. This means RM 1 is loaded (`rm_shift_right`). It may also appear as `RM_ID` (bits 24:8) = 0. This means RM 0 is loaded (`rm_shift_left`).
- `SHUTDOWN` (bit 7) = 0. This VSM is not in the shutdown state.
- `ERROR` (bits 6:3) = 0000. There are no errors.
- `STATE` (bits 2:0) = 111. The Virtual Socket is full.

The status of `vs_count` is 129, which is 0000_0000_0000_0000_1000_0001 in binary.

- `RM_ID` (bits 23:8) = 0. This means RM 0 is loaded (`rm_count_up`).
- `SHUTDOWN` (bit 7) = 1. This VSM is in the shutdown state.
- `ERROR` (bits 6:3) = 0000. There are no errors.
- `STATE` (bits 2:0) = 001. `RM_SHUTDOWN_ACK` is 1, as this VSM is executing the hardware shutdown step.

These explicit details are reported in the breakdown of the status register in the return value from this Tcl proc.

- Send a software trigger to the Shift Virtual Socket.

```
prc_send_sw_trigger vs_shift 0
prc_send_sw_trigger vs_shift 1
```

Remember that values of 0 and 2 correspond to shift left, and values of 1 and 3 correspond to shift right, as defined during PRC customization.

- Check the configurations of the RMs for the Count Virtual Socket.

```
prc_show_rm_configuration vs_count 0
prc_show_rm_configuration vs_count 1
```

The values for the bitstream sizes and address are reported here. These values could then be modified to account for necessary adjustments to the size or location of the bitstream. Different indices can be added to insert new RMs. Note that this query cannot be done for `vs_shift`, as the `vs_shift` VSM is not in the shutdown state.

- Move the Count Virtual Socket Manager into active mode.

```
prc_restart_vsm_no_status vs_count
```

The Count Up and Count Down pushbuttons can now be used to load these partial bitstreams using the PR Controller.

Step 7: Modifying the PRC in the FPGA

In the final step, you add a new Reconfigurable Module to the Shifter VSM. In the `create_prom.tcl` script, you can see that two black box modules have already been generated. These represent two new RMs that may have been created after the static design was deployed to the field. You modify the PRC settings to access one of these RMs by assigning the size, address, properties and trigger conditions.

- Shut down the Shift VSM so it can be modified.

```
prc_shutdown_vsm vs_shift
```

- Check the status of the first three RM IDs to see their register bank assignments.

```
prc_show_rm_configuration vs_shift 0
prc_show_rm_configuration vs_shift 1
prc_show_rm_configuration vs_shift 2
```

Currently, RM ID 2 has the same mapping as the partial bit file for RM ID 0, so the same shift left partial bitstream would be loaded. This is the behavior as requested when the initial trigger mapping was done during core customization.

- When the MCS file is created for the prom, it adds additional blanking RMs that are already loaded into the BPI flash. Use this sequence of commands to reassign the trigger mapping for slot 2 to point to the blanking Reconfigurable Module for `vs_shift`.

```
prc_write_register vs_shift_rm_control2 0
```

This defines the settings for the `RM_CONTROL` register for slot 2. No shutdown, startup, or reset are required. Note how for the other two slots, the differing reset durations lead to different control values.

```
prc_write_register vs_shift_rm_bs_index2 327684
```

This assigns a new bitstream reference for this RM ID.

```
prc_write_register vs_shift_trigger2 2
```

This assigns the trigger mapping such that trigger index 2 retrieves RM 2. The `RM_BS_INDEX` register within the PR Controller is 32 bits but is broken into two fields. UltraScale devices require clearing and partial bitstreams. These bitstreams are identified separately with unique IDs, but referenced together in this field.

This value of 327684 converts to 0000000000000101_000000000000100 in binary. Or more simply, ID 5 for the upper 16 bits for the `CLEAR_BS_INDEX` and ID 4 for the lower 16 bits for the `BS_INDEX`. This assignment sets the clearing and partial bitstream identifiers at the same time.

```
prc_show_rm_configuration vs_shift 2
```

This shows the current state of RM ID 2. Note the changes from the prior call to this command.

4. Complete the RM ID 2 customization by setting the bitstream details.

```
prc_write_register vs_shift_bs_size4 375996
prc_write_register vs_shift_bs_address4 12935168
prc_write_register vs_shift_bs_size5 26036
prc_write_register vs_shift_bs_address5 13312000
```

5. Restart the VSM and then issue trigger events to it using software, as there is no pushbutton assigned for slot 2.

```
prc_restart_vsm_no_status vs_shift
prc_send_sw_trigger vs_shift 2
```

Switch between values of 0, 1 and 2 to reload different partial bitstreams.

Note that this same sequence of events could not be performed for the Count VSM as it is currently configured, even knowing that the PROM image has a Count black box partial bitstream sitting at address 13338624 with a size of 274104. During PRC customization, this VSM was selected to have only 2 RMs allocated, so expansion is not permitted.

Conclusion

This concludes lab 6. In this lab, you:

- Customized the Partial Reconfiguration Controller IP.
- Created Virtual Sockets and added RMs to them.
- Compiled the design and created a PROM file.
- Programmed the linear flash on the VCU108 board.
- Used pushbuttons to issue hardware triggers.
- Used the AXI-Lite interface to check the core status and issue software triggers.
- Added a new RM to an already deployed design.

Overview

This lab covers the details of a demonstration that targets the KCU116 or VCU118 demo board. It is a modified version of the design used in Lab 6: Partial Reconfiguration Controller IP for UltraScale Devices and is enhanced with these features:

- Software-driven triggering and bitstream management via MicroBlaze
- Partial bitstream delivery from QSPI or DDR4 memory
- Compatibility with Soft Error Mitigation (SEM) IP
- Per-frame CRC checking
- Additional debug capabilities

It retains the PR Controller and PR Decoupler IP from the base design as well.

Note that the VCU118 must be version 2.0 (or newer) with the dual quad SPI flash. Version 1.x and earlier boards have Micron MT28G BPI flash which is being discontinued.

Step 1: Extracting the Tutorial Design Files

1. To obtain the tutorial design file, see Tutorial Design Description.
2. Navigate to `\prc_usp` in the extracted files. The `prc_usp` data directory is referred to throughout the lab as the `<Extract_Dir>`.

Step 2: Processing the Tutorial Design

The purpose of this design is the end run-time functionality and software management, not design processing, so the details of the implementation flow are not extensively covered here. For a review of the Partial Reconfiguration design flow, refer to earlier labs in this document.

1. Extract the tutorial design archive.
2. From a command shell, launch Vivado with the example design project creation script. This must be launched from the top level of the design archive where this script is located.

```
vivado -mode tcl -source project_prc_kcu116.tcl
```

or

```
vivado -mode tcl -source project_prc_vcu118.tcl
```

3. When the script completes, open the Vivado GUI by typing the following:

```
start_gui
```

4. Check to see if IP needs to be updated. Run **Reports > Report IP Status** and update any out-of-date IP.

A few minor revision changes, such as for ILA, might be found if using a newer version of Vivado. Use the default setting, which has the core container disabled, but skip the actual synthesis of the IP module – this will be done during the next step.

5. In the Flow Navigator, click on **Run Implementation** to pull the design all the way through synthesis and implementation.

While place and route is running, take a look at the design. The top level is basically the LED-Shift-Count design that is the base of the other lab in this tutorial. This version has a block diagram (mb_prc) inserted that takes care of a few functions within an AXI subsystem:

- A MicroBlaze is the center of design management, connecting to a user interface via uart.
- The PR Controller IP manages the PR events. An ILA core and a timer give some visibility into what’s happening in there.
- DDR4 and QSPI interfaces are in this part of the design.

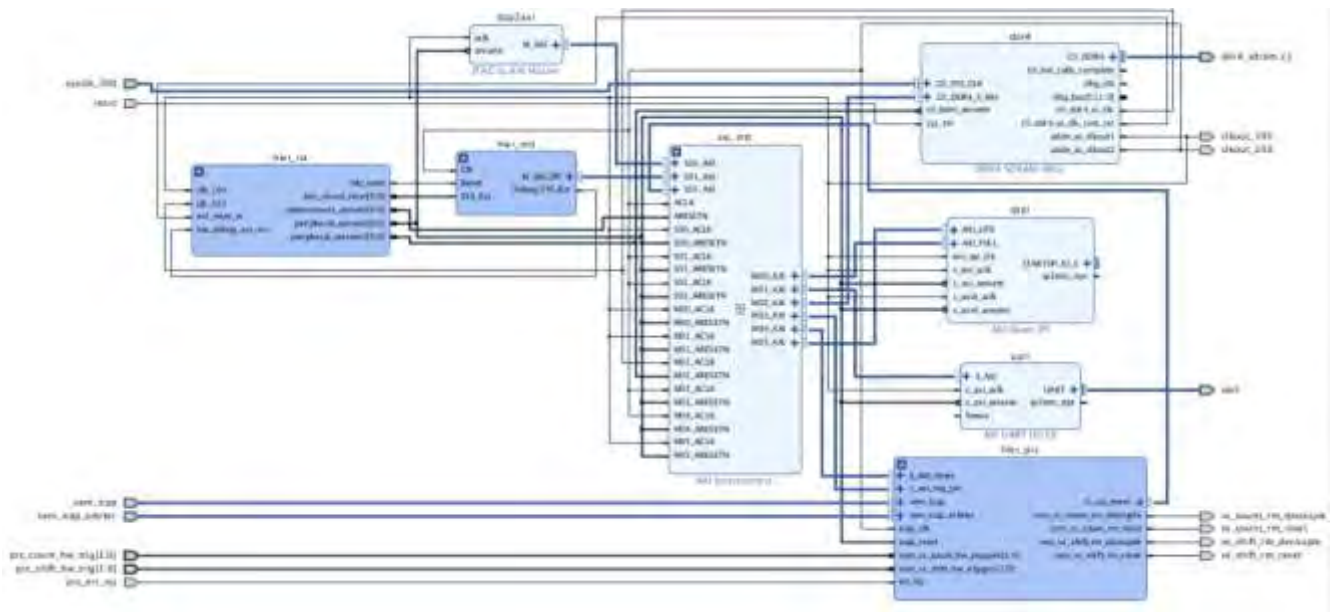

Figure 95: Block Diagram for Partial Reconfiguration management

The top level design instantiates the shift and count reconfigurable modules and also houses the SEM IP. The details of the SEM IP instantiation differ between Virtex UltraScale+ and Kintex UltraScale+, as the VU9P is an SSI device. Multiple instantiations (one per SLR) of the FRAME_ECC component are required for SSI support.

6. When implementation completes, do not generate bitstreams. Click **Cancel** in the pop-up dialog.
7. Select **File > Export > Export Hardware** then click **OK** to build a design image for SDK.
8. Select **File > Launch SDK** then click **OK** to compile the software for this example design.
9. In SDK, select **File > New > Application Project** to create a new application project.
10. Name the new project `prc_demo` and click **Next**. Select **Empty Application** and then **Finish**.

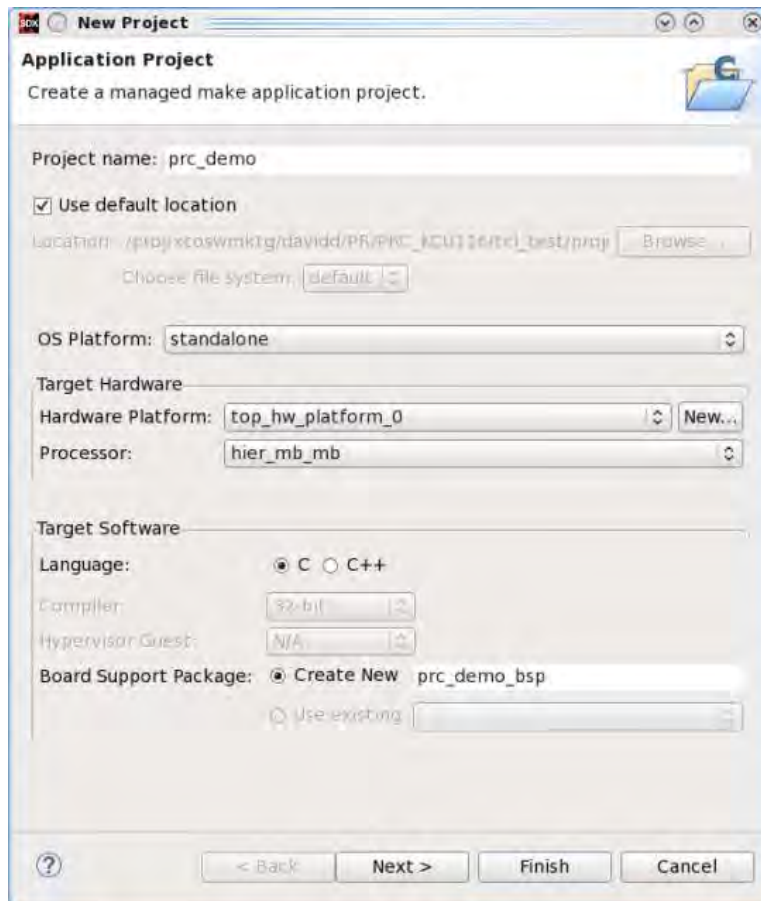

Figure 96: Create a new Application Project in SDK

11. In the Project Explorer window, expand **prc_demo**. Right click on `src` and select **Import**. Select **General** then **File System** and click **Next**. Browse to the `sources/prc_demo/src` directory and click **OK**. Finally, check all six `.c` and `.h` sources in that folder and click **Finish**.

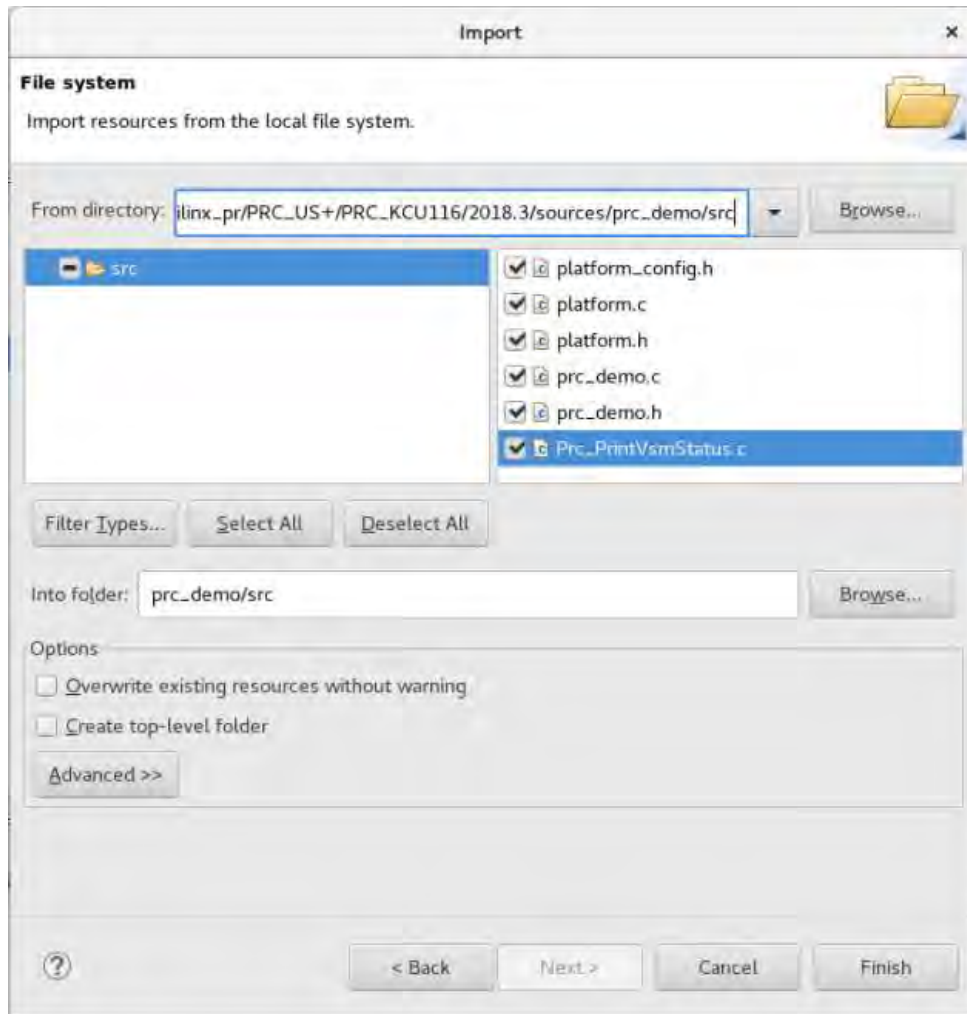

Figure 97: Sources for the SDK project

When these files are added, `prc_demo.elf` is automatically created. If any changes are made to these sources or settings, this file will be automatically updated.

12. Expand the `src` directory and open `prc_demo.c`. This file contains most of the software code that you will see later. The locations and sizes of the partial bitstreams are stored in `prc_demo.h`. The calculations can be seen in `prc_bitstream_sizes_lab7.xlsx`.
13. Exit SDK.
14. In the Vivado IDE project, select **File > Add Sources**.
15. Select Add or create design sources, then click Next.
16. Add `prc_demo.elf` from the `project_prc_$board/prc_demo/Debug` folder. Leave the **Copy sources into project** option deselected and click **Finish**.
17. Right click on `prc_demo.elf` and select **Associate ELF Files**. Because the design is already compiled, select **Skip Generate**.

18. In the window that appears, change the top reference for Design Sources to the `prc_demo.elf` file that was just added. Then click **OK**.

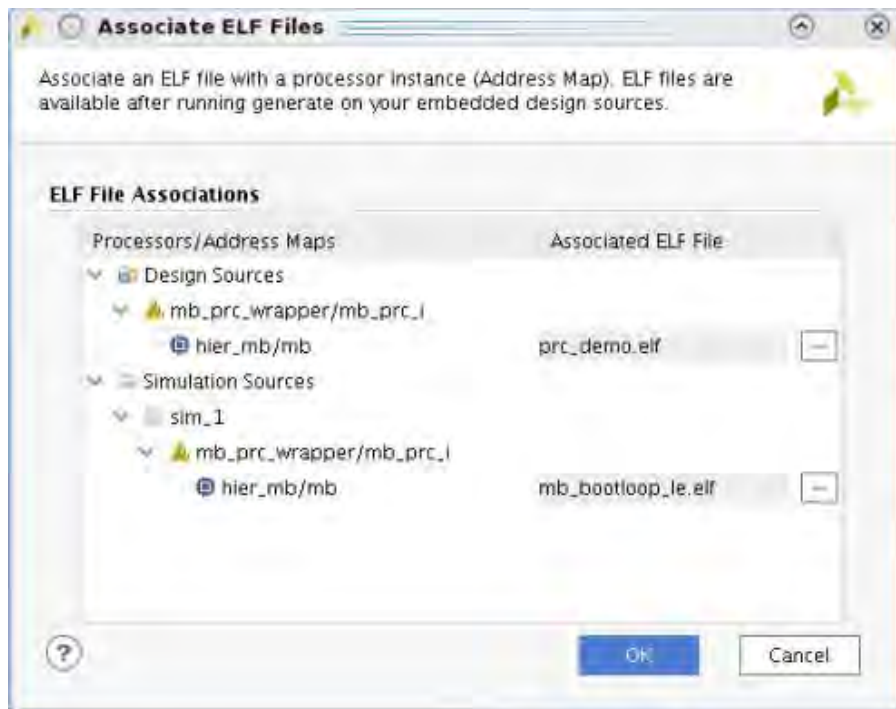

Figure 98: Associate the `prc_demo.elf` file with the MicroBlaze instance

19. Right click on `impl_1` and select **Generate Bitstream**.

This action creates the full bitstream (containing the MicroBlaze code in the .elf file) for the Shift Right – Count Up configuration, along with partial bitstreams for each of the Reconfigurable Modules. Only the full configuration bitstream from the parent run will be used here, so there is no need to generate bitstreams from the `child_0_impl_1` run. Note that the sizes for all partial bitstreams are reported, in bits, in the log.

20. Source this script to create all bit files. In the Tcl Console, make sure you are currently in the level above the `project_prc_<board>` directory, where this script exists.

```
source create_all_bitstreams_kcu116.tcl
```

or

```
source create_all_bitstreams_vcu118.tcl
```

Settings for full versus partial bitstreams must be different to account for the configuration modes and options in this design. This is done within a Tcl script that copies the full bitstream created in the prior step, and then creates all the partial bitstreams that are necessary for all Reconfigurable Modules.

Important: *Users are not yet able to set different options for full versus partial bitstreams in project mode in the Vivado IDE. This feature is planned for a future Vivado release and is expected to be shown as a new page in the Partial Reconfiguration Wizard.*

Examining this script shows that the CONFIG_MODE must change from the default of SPIx4 for the initial configuration to SELECTMAP32 for the partial bitstreams, which are delivered to the ICAP. Two versions of partial bitstreams are generated, with and without the per-frame CRC feature enabled.

21. Source one of these two scripts to create PROM images for the target board.

```
source create_prom_file_kcu116.tcl
```

or

```
source create_prom_file_vcu118.tcl
```

This creates a QSPI boot image with the full bitstream followed by all the partial bitstreams. The addresses listed in this script are calculated based on the size of each partial bitstream. Note that the sizes for all partial bitstreams are reported, in bytes, in the log. The calculations can be seen in `prc_bitstream_sizes_lab7.xlsx`.

Step 3: Running the Tutorial Design

Once all the bitstreams and prom images have been created, you can run the design on hardware. There are a number of different features that can be demonstrate. There is no specific order in which these demonstrations must be done after the device has been programmed.

Program the QSPI Flash Device

1. Connect the target board to your computer and power the board on. Connect to both micro-USB ports for JTAG and UART connections.
2. Program the configuration memory device (QSPI).
 - a. Open the Vivado Hardware Manager and connect to the target board.
 - b. Right click on the device and select Add Configuration Memory Device
 - c. Select the Micron **mt25qu01g** that supports x1, x2 and x4 modes.

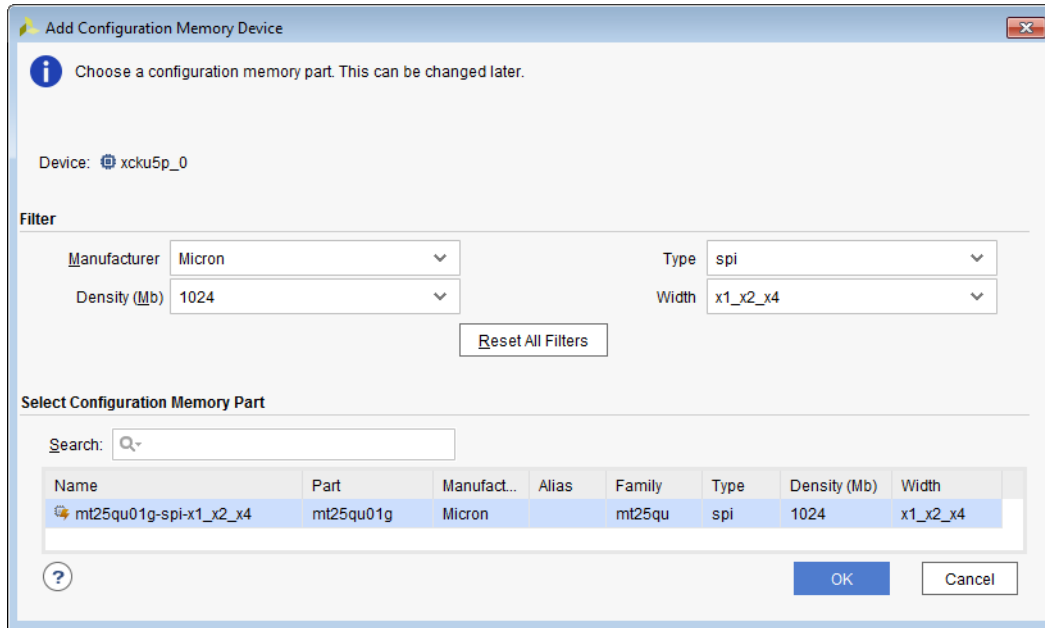

Figure 99: Program the QSPI flash

- d. When prompted, add a programming file. The target file is the `pr_prom.mcs` from the `Bitstreams` folder in the project directory.
3. After the PROM has been programmed, use the PROG button to reconfigure the FPGA from this boot flash.

The pushbuttons can control actions in the FPGA design. The left and right buttons load shift left and shift right partial bitstreams, respectively. The up and down buttons load count up and count down partials, respectively. Do not push the center button yet.

Manage Reconfiguration via Software

4. Open a UART terminal to communicate with the software running in MicroBlaze.
 - a. Set the COM port to an appropriate value for your computer
 - b. Set the Baud Rate to **115200**.
 - c. Press the PROG button on the board to restart the design with the UART terminal open.

Note: If you need a USB to UART driver for your terminal, see *Silicon Labs CP210x USB-to-UART (UG1033)*.

Notice that all the partial bitstreams are copied from the QSPI flash over to the DDR4 memory. Then the software menu appears:

```

COM22:115200baud - Tera Term VT
File Edit Setup Control Window Help
Copying QSPI content to DDR4...

*** Partial Reconfiguration SW Trigger ***
-----
Menu
Reconfig Type: Normal CRC from QSPI
1: Shift Left
2: Shift Right
3: Count Up
4: Count Down
5: Put RPs in Active mode
6: Put RPs in Shutdown mode
7: Change CRC type of Partial bit
8: Change Storage of Partial bit
9: Report Status
0: Exit
>
  
```

Figure 100: The `pr_demo` software application running

The menu options allow you to:

- **1-4:** These are the four trigger options to load partial bitstreams to the ICAP via the PR Controller. These mimic the pushbuttons on the board.
- **5-6:** These toggle the PR Controller status between active and shutdown mode for both RPs. When the RPs are in shutdown mode, triggers (software or hardware) are ignored.
- **7:** This toggles the partial bitstreams used between standard partials and those instrumented with per-frame CRC checks.
- **8:** This toggles the partial bitstream source between QSPI and DDR4 memory storage.
- **9:** Reports the current status of each Virtual Socket.

As you walk through these different features, the software will give feedback. Note that reconfiguration time is reported each time PR is executed from within the software.

Monitor Partial Reconfiguration via Debug Cores

Vivado debug cores have been inserted in this design, allowing you to monitor activity during partial reconfiguration events. A key detail for configuring via the ICAP is to have prepared the partial bitstreams with the right bit and byte ordering for each `.bin` file.

5. In the Vivado Hardware Manager, refresh the device to find all the Vivado Debug cores. There are three ILA cores, one VIO core and one MIG core in this design.

6. In one of the ILA core windows, click the **Specify the probes file** links to find Bitstreams/top_count_up_shift_right.ltx. Click **OK** then **Refresh**.
7. In **hw_ila_2**, click the + to add probes in the Trigger Setup window.
8. Select **SLOT_2_ICAP_i_1[31:0]** and click **OK**. Change the Radix to **[H]** for hexadecimal.
9. Set the trigger in the Trigger Settings window to a value of **5599_AA66**, which is the configuration sync word, bit-swapped.
10. Set the trigger position in the Settings window to **980**.
11. Select the **Run Trigger** button in the Hardware Manager GUI.

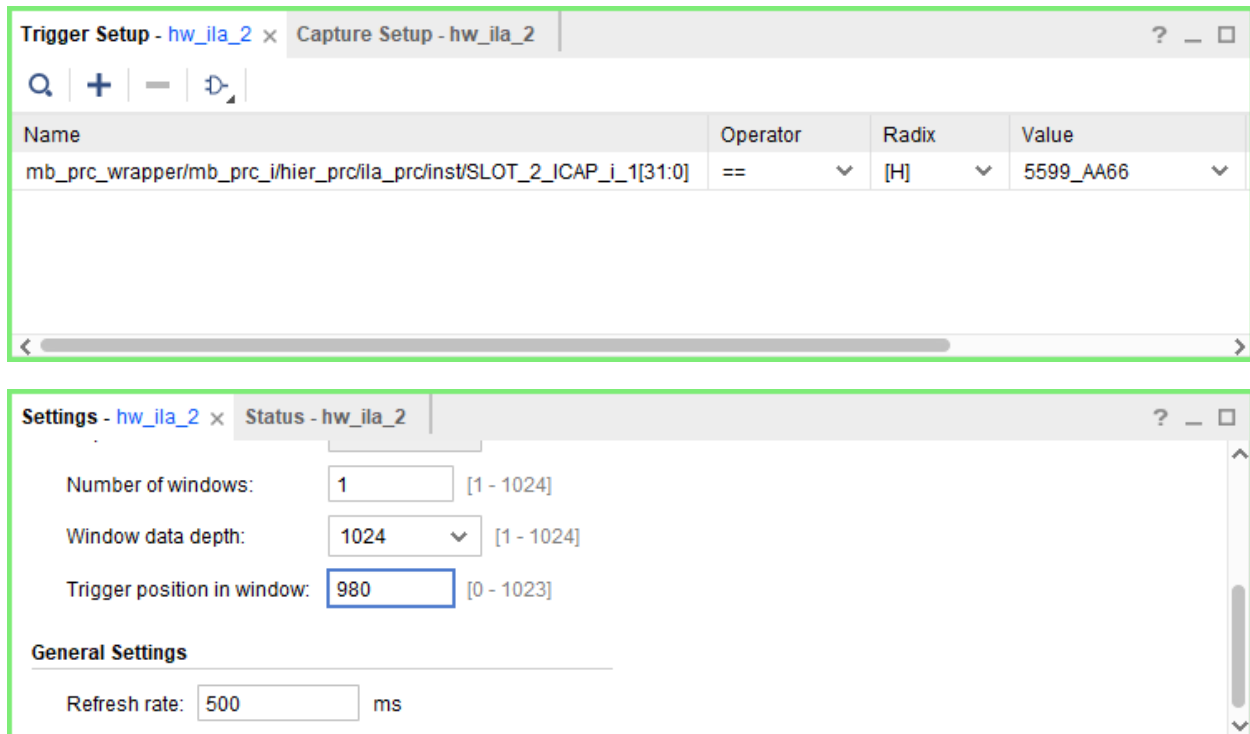

Figure 101: ICAP input capture settings for sync word

12. On the board, push one of the pushbuttons other than the center to trigger reconfiguration of the shifter or counter. Or, perform this action via the UART terminal.
13. In the resulting captured waveform, note a few things:
 - o Far to the left, one of the rm_decouple signals (depending on which Reconfigurable Partition you have chosen to reconfigure) has transitioned from low to high. This isolation is initiated in the design prior to partial bitstream delivery
 - o The sync word is preceded by 000000dd and then 88440022, which are the bit-swapped bus width detection

- The ICAP output transitions from fffff9b (no sync, no error) to fffffdb (sync, no error). This transition shows recognition of the sync word, and the configuration engine is now expecting bitstream data.
- PRDONE transitions high to low much further to the right, out of the range of this captured waveform.

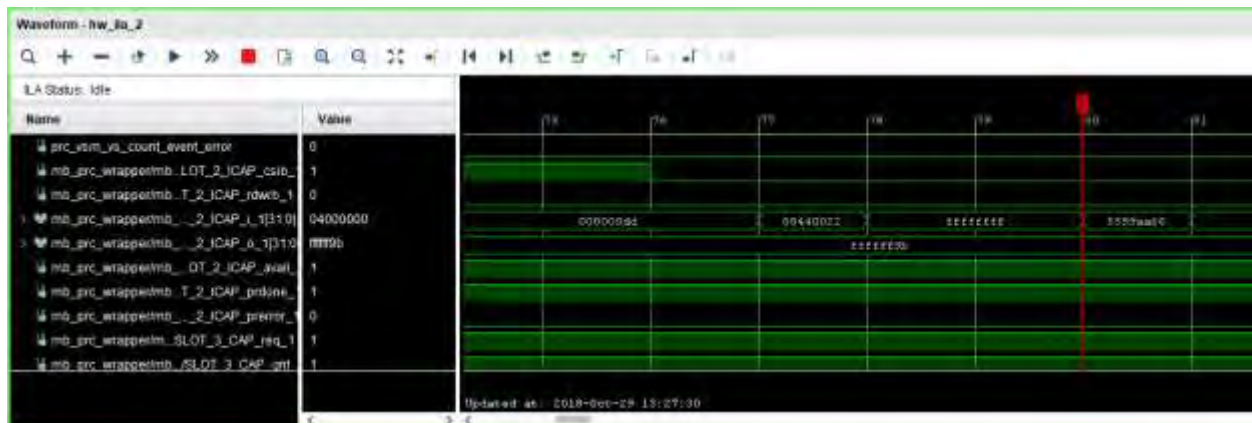

Figure 102: Waveform capture of sync word entering ICAP

Note: Bitstreams will have multiple sync-desync pairs, as they are constructed via multiple segments. Multi-SLR devices, for example, have more due to bitstream formatting per SLR.

14. Change the Value of the ICAP_i port to **0000_00B0**, which is the desync word, bit-swapped.
15. Set the trigger position in window to **512**.
16. Arm the trigger again and issue a partial reconfiguration.
17. The resulting waveform shows the end of this part of the reconfiguration sequence, and shows PRDONE going high a few clock cycles after the desync word was seen.

Insert CRC failures and View the FPGA Response

Partial bitstreams with and without per-frame CRC checking were created and loaded into the QPSI flash as part of the PROM file. The design can insert CRC failures by swapping some bits in the CRC value just prior to loading the file into the ICAP. Any uncompressed – using bitstream generation property, not the PR Controller feature – partial bitstream can have an error injected in this manner to see how the device responds. This is controlled via the center pushbutton.

18. If not done in the prior section: In the Vivado Hardware Manager, refresh the device to find all the Vivado Debug cores.
19. There are three ILA cores, one VIO core and one MIG core in this design.
20. If not done in the prior section: In one of the ILA core windows, click the **Specify the probes file** links to find `Bitstreams/top_count_up_shift_right.ltx`.

21. Click **OK** then **Refresh**.
22. In **hw_ila_2**, click the **+** to add probes in the Trigger Setup window.
23. Select **icap_err_inserted** and click **OK**.
24. Set the trigger in the Trigger Settings window to rising edge of **icap_error_inserted**.
25. Set the trigger position in the Settings window to **512**.
26. Push the **Run Trigger** button in Hardware Manager GUI.

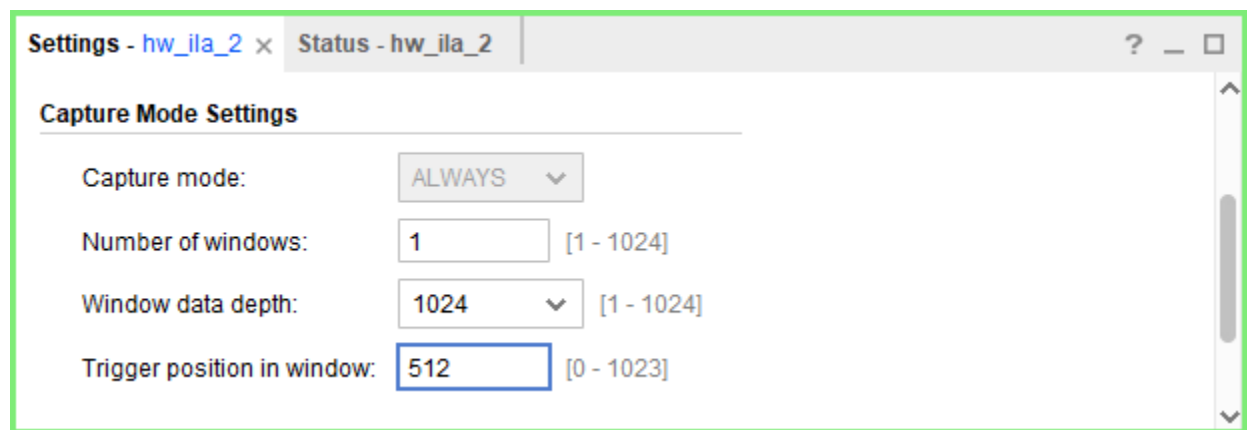

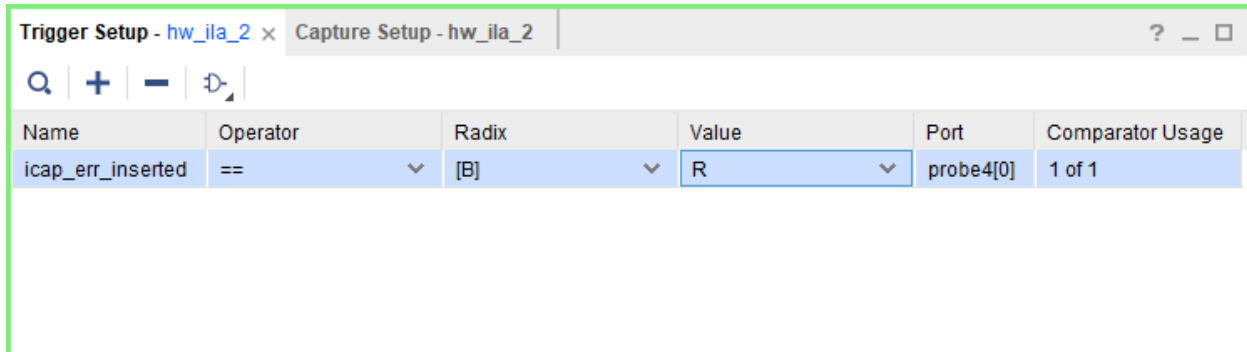

Figure 103: Trigger setting for icap_err_inserted

27. In the UART terminal, set Reconfig Type as Normal CRC from DDR4. This is the default setting.

```

----- Menu -----
Reconfig Type: Normal CRC from DDR4
1: Shift Left
2: Shift Right
3: Count Up
4: Count Down
5: Put RPs in Active mode
6: Put RPs in Shutdown mode
7: Change CRC type of Partial bit
8: Change Storage of Partial bit
9: Report Status
0: Exit
>
    
```

Figure 104: Design ready to reconfigure from DDR4 without inserted CRC

28. Push the center pushbutton, and then reconfigure the module you'd like via pushbutton or the UART terminal. The CRC value at the end of the partial bitstream is swapped to cause a CRC error. As a result, INIT_B goes low (the INIT_B LED turns red), indicating a CRC error.

Note: On the KCU116 board, the INIT_B LED is on the underside of the board.

29. In ILA Waveform, the trigger location marks where **icap_err_inserted** is asserted. After the error insertion, you will see PRERROR then PRDONE goes high. Also, the **rm_decouple** signal is high throughout, indicating the Reconfigurable Partition is still isolated.

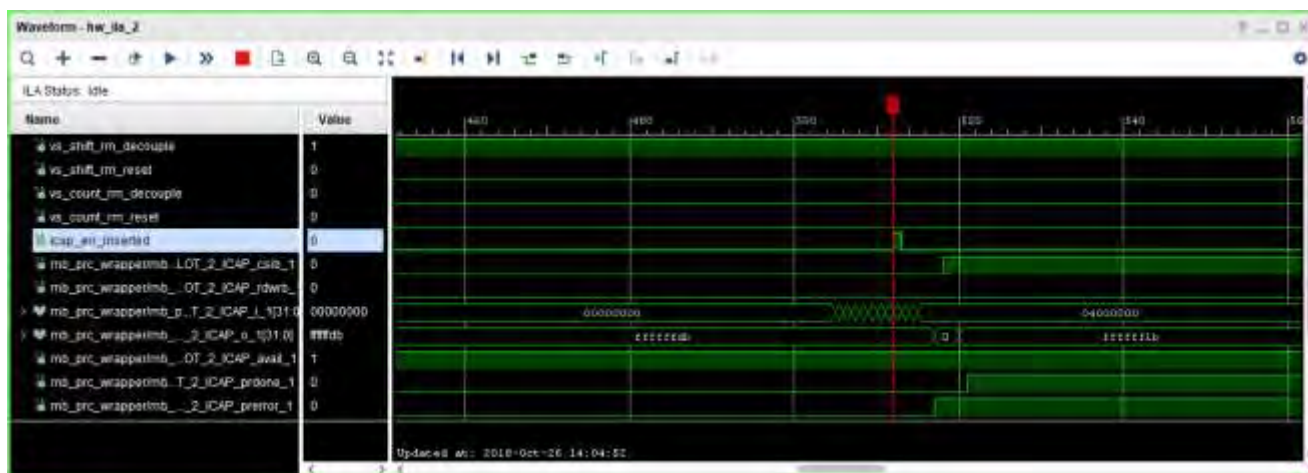

Figure 105: Waveform capture showing icap_err_inserted, PRERROR, PRDONE, and decouple asserted

Note: The *prc_vsm_vs_*_event_error* signal is low in this waveform, but it will be pulsed outside of captured waveform because of the latency in PR Controller.

If the CRC error is found using the standard CRC, which only occurs at the end of the partial bitstream, the incorrect bitstream has already been loaded into the device. There is no way to know where any incorrect bits exist, or if they will disrupt the reconfigurable or static design. The only way to be sure of a full recovery from this condition is to perform a full reconfiguration of the device. In this tutorial, only the CRC value is swapped, so we can be assured that the error has not affected the static design.

30. When CRC error occurred, the PR Controller entered shutdown mode. In the UART terminal, **Report Status** (option 9) shows the RP is in shutdown mode and it reports a BS ERROR. To recover from this error status, return the RP to active mode by selecting **Put RPs in Active Mode** (option 5) from the terminal, and reconfigure with a correct partial bit file. Then INIT_B returns high (LED turns green) and the design is now back to normal operation.

Next, try with per-frame CRC values inserted.

31. In the terminal, set the Reconfig Type to per Frame CRC (option 7).

32. In the Hardware Manager, re-arm the trigger by clicking the **Run Trigger** button. Then perform partial reconfiguration from the terminal or via pushbutton

33. In the ILA waveform, you can see the error has been inserted in the first frame of partial bitstream – you can see partial reconfiguration starts soon after vs_rm_*_decouple goes high. However, when using per-frame CRC, the error inserted frame has not been loaded into the device yet, so there is no need for a reconfiguration of the full design, just reconfigure the incomplete Reconfigurable Partition with a valid partial bitstream. To recover from the error status, repeat the procedure from step 8.

Conclusion

This concludes lab 7. In this lab, you:

- Implemented an UltraScale+ version of a design with the Partial Reconfiguration Controller.
- Compiled a MicroBlaze core with software that manages partial reconfiguration events.
- Programmed the QSPI on the KCU116 or VCU118 board.
- Used a UART interface to manage partial reconfiguration from QSPI or DDR4 memory.
- Inserted bitstream delivery errors to see CRC checking capabilities.

NOTE: *Although an SEM core exists within the design, it is not exercised during hardware testing in this lab. If the SEM core is running on hardware to detect upset events, it must be paused before performing partial reconfiguration.*
