AXI Video Direct Memory Access (axi_vdma) v5.00.a

Introduction

The Advanced eXtensible Interface (AXI) Video Direct Memory Access (AXI VDMA) core is a soft Xilinx Intellectual Property (IP) core providing high-bandwidth direct memory access between memory and AXI4-Stream-video type target peripherals. Initialization, status, and management registers are accessed through an AXI4-Lite slave interface.

Features

- AXI4 Compliant
- Primary AXI4 Memory Map data width support of 32, 64, 128, 256, 512, and 1024 bits
- Primary AXI4-Stream data width support of 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, and 1024 bits
- Register Direct Mode
- Optional independent Scatter Gather Direct Memory Access (DMA) support
- Optional Data Re-Alignment Engine
- Optional Genlock Synchronization
- Optional Line Buffers and Store-And-Forward
- Independent, asynchronous channel operation
- Dynamic clock frequency change of AXI4-Stream interface clocks
- Dynamic line buffer threshold
- Optional flush on frame sync
- Optional frame advancement on error
- Optional fsync crossbar, fstores 32, and internal Genlock

Support

Provided by Xilinx @ <u>www.xilinx.com/support</u>

- 1. For a complete list of supported EDK derivative devices, see IDS Embedded Edition Derivative Device Support.
- 2. For a complete listing of supported devices for IP cores, see the release notes for this core.
- 3. Contains few Verilog files. Top level is VHDL.
- 4. Standalone driver information can be found in the EDK or SDK installation directory.

See xilinx_drivers.htm in <install_directory>/doc/usenglish. Linux OS and driver support information is available from http://wiki.xilinx.com.

5. For the supported versions of the tools, see the <u>ISE Design Suite 13:</u> <u>Release Notes Guide</u>.

Chapter 1

Overview

Many Video applications need a frame buffer to handle things like rate changes or changes to the image dimensions (that is, scaling). The AXI VDMA is designed to allow for efficient high bandwidth access between AXI4-Stream-video data and AXI4 Memory Mapped data, which is typically connected to external storage such as an external DDR2 memory.

The AXI VDMA core has four AXI4 Memory Map interfaces: AXI4-Lite Slave, AXI4 Memory Map Read Master, AXI4 Memory Map Write Master, and AXI4 Memory Map Scatter Gather Read Only Master. Associated with the memory map interfaces are two AXI4-Stream interfaces: AXI Memory Map to Stream (MM2S) Stream Master, AXI4-Stream to Memory Map (S2MM) Stream Slave.

Optional Genlock and Video Frame Sync interfaces are also provided for each channel.

Register access and configuration are provided through the AXI4-Lite slave interface. The register module provides control and status for DMA operations.

Primary high-speed DMA data movement between system memory and the stream target is through the AXI4 Memory Map Read Master to AXI MM2S Stream Master and AXI S2MM Stream Slave to AXI4 Memory Map Write Master. The AXI DataMover is used for high throughput transfer of data from memory to stream and from stream to memory. The MM2S channel and S2MM channel operate independently and in a full duplex like method. The AXI DataMover provides the AXI VDMA with a 4 Kbyte address boundary protection and automatic burst partitioning. It also provides the ability to queue multiple transfer requests using nearly the full bandwidth capabilities of the AXI4-Stream buses. Furthermore, the AXI DataMover provides byte-level data realignment, allowing memory reads and writes to any byte offset location.

Register Direct Mode

The AXI VDMA provides a Register Direct Mode that allows the processor to directly control the operation of the core. In this mode the video parameter registers and start address registers are accessible through the Slave AXI4-Lite control interface. Figure 1-1 illustrates the AXI VDMA configured for Register Direct Mode.

www.xilinx.com

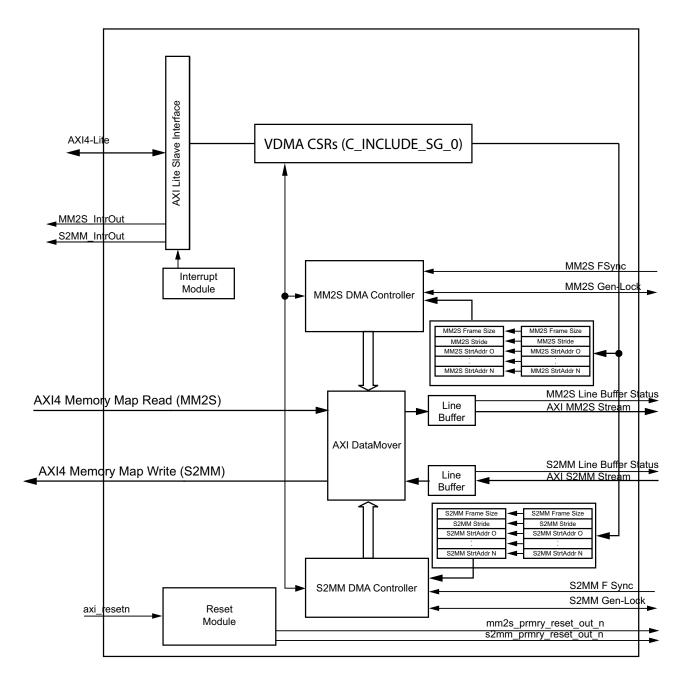

Figure 1-1: Block Diagram of AXI VDMA in Register Direct Mode

Scatter Gather Mode

The AXI VDMA provides an optional Scatter Gather Mode for off-loading processor management tasks to hardware. The Scatter Gather Engine fetches and updates buffer descriptors from system memory through the AXI4 Memory Map Scatter Gather Read/Write Master interface. Figure 1-2 illustrates the AXI VDMA configured for Scatter Gather Mode.

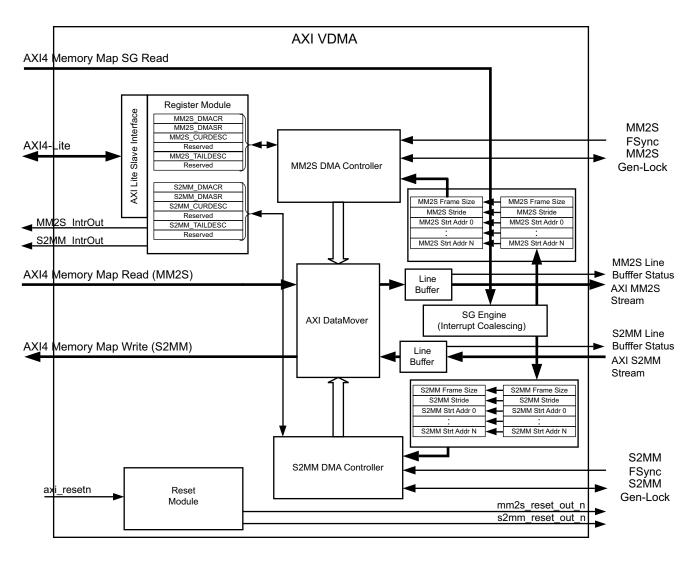

Figure 1-2: Block Diagram of AXI VDMA in Scatter Gather Mode

Typical System Interconnect

The AXI VDMA core is designed to be connected via AXI Interconnect in the user's system. Figure 1-3 illustrates a typical MicroBlaze[™] processor configuration with an optional AXI SG connection that is only present in Scatter Gather Mode. In Register Direct Mode, the processor directly controls the operation of the core by accessing the video parameter and start address registers through the AXI4-Lite interface. In Scatter Gather mode, the processor indirectly controls the operation of the core by accessing the control registers of VDMA through the AXI4-Lite interface. The Scatter Gather engine then fetches buffer descriptors from external memory which contain the video parameters and start addresses. The dual interrupt output of the AXI VDMA core is routed to the System Interrupt Controller.

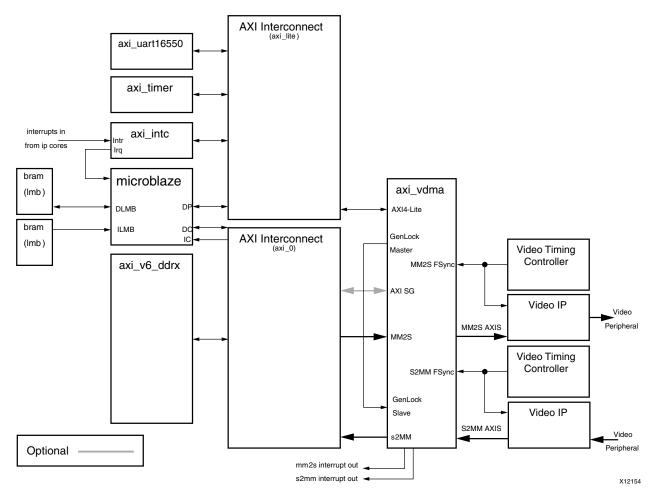

Figure 1-3: Typical MicroBlaze Processor System Configuration

Feature Summary

AXI4 Compliant

The AXI VDMA core is fully compliant with the AXI4 Memory Map interface, AXI4-Stream interface and AXI4-Lite interface.

AXI4 Memory Map Data Width

The AXI VDMA core supports the primary AXI4 Memory Map data bus width of 32, 64, 128, 256, 512, and 1024 bits.

AXI4-Stream Data Width

The AXI VDMA core supports the primary AXI4-Stream data bus width of 8, 16, 24, 32, 48, 64, 96, 128, 192,256, 384, 512, 768 and 1024 bits. The AXI4-Stream data width must be less than or equal to the AXI4 Memory Map data width for the respective channel.

Register Direct Mode

The AXI VDMA core supports register direct mode in which the transfer descriptors are placed in the control register map along with the video-specific registers. In this mode, the independent SG AXI4 Memory Map bus is not used for fetching and updating of transfer descriptors.

Scatter Gather Mode

The AXI VDMA core supports fetching and updating of transfer descriptors via the independent SG AXI4 Memory Map bus. This allows descriptor placement to be in any memory-mapped location separate from data buffers.

Data Realignment Engine

The AXI VDMA core supports the optional Data Realignment Engine (DRE). When the DRE is enabled, the DRE Width matches the associated Payload Stream interface width up to 64 bits.

Genlock Synchronization

The AXI VDMA core supports Genlock synchronization. Each channel of AXI VDMA can be designed to operate as either a Genlock Master or Slave. By using this feature, the master and slave are kept in sync by not allowing both to use the same buffer at the same time.

The AXI VDMA core also supports an optional internal Genlock Bus. This allows an internal connection of the Genlock bus, which gives the user the option to not connect a Genlock bus externally between mm2s and s2mm channels. A DMACR register control bit (bit 7) is also added to allow dynamic selection of internal or external Genlock for channels configured as a Genlock Slave.

Line Buffers and Store and Forward

The AXI VDMA core supports an optional line buffer that can be utilized to prevent memory controller throttling from causing inner packet throttling on the stream interface.

The AXI VDMA core also supports the optional Store-And-Forward feature. On MM2S, this prevents the channel from requesting more read data than can be held in the Store-And-Forward buffer. On S2MM this prevents the channel from issuing write requests when there is not enough data in the Store-And-Forward buffer to complete the write.

Asynchronous Channels

The AXI VDMA core supports asynchronous clock domains for AXI4-Lite, AXI Scatter Gather (SG), S2MM AXI4-Stream interface, MM2S AXI4-Stream interface, S2MM AXI4 Memory Map interface and MM2S AXI4 Memory Map interface.

Frame Sync on TUSER0

The AXI VDMA supports an optional TUSER bus on both MM2S and S2MM AXIS interfaces with TUSER(0) being used for a Start of Frame (SOF) or external frame sync. When enabled (C_MM2S_SOF_ENABLE=1), MM2S channel will drive frame sync out on m_axis_mm2s_tuser(0). When enabled (C_S2MM_SOF_ENABLE=1), S2MM channel will sync to frame sync in on s_axis_s2mm_tuser(0).

Frame Sync Crossbar

This feature allows routing of an AXI VDMA frame sync source to both channels. Control bits are added to the DMACR (bits 5 and 6) of both channels for selecting the respective channels frame sync source. This feature is only available when C_USE_FSYNC = 1.

32 Frame Stores

Support for the number of frame stores has been increased from 16 to 32 for each channel. For SG =1 mode, it increases the maximum length of the descriptor chain from 16 to 32 (for each channel). For SG=0 mode, it increases the maximum value of Frame Store Start Address registers from 16 to 32 (for each channel). In this mode, MM2S_REG_INDEX and S2MM_REG_INDEX are added to create another set of register bank of 16 frame stores. This is done to keep it backward compatible with AXI VDMA previous versions.

Additional Stream Data Width Values Support

AXI VDMA v5_00 supports increased allowable Stream Data width values. They are 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, and 1024 for both MM2S and S2MM channels independently.

Dynamic Clock Frequency Change of AXI4-Stream Interface Clocks

The AXI VDMA core allows the user to change the primary datapath clocks dynamically to support different video resolutions without rebuilding the system.

Dynamic Line Buffer Threshold

This feature allows the almost empty and almost full threshold values to be dynamically changed by accessing new threshold registers.

Flush on Frame Sync

The flush on frame sync feature allows AXI VDMA to reset internal states and flush transfer data on frame sync for certain error conditions. This allows AXI VDMA to restart transfers at the beginning of the next new frame after DMA Internal error detection instead of halting the channel.

Optional Frame Advancement on Error

When an error is detected in a particular frame, this optional feature allows the user to let the frame number advance on the next frame sync or not advance and reuse the errored frame's frame number.

Applications

The AXI VDMA core provides high-speed data movement between system memory and AXI4-Stream-based target Video IP.

Unsupported Features

The following AXI4 features are not supported by the AXI VDMA design.

- User signals on AXI Memory Map Interface
- Locked transfers
- Exclusive transfers
- FIXED and WRAP Burst transfers

Licensing

This Xilinx® LogiCORE[™] IP module is provided at no additional cost with the Xilinx Integrated Software Environment (ISE®) Design Suite Embedded Edition software under the terms of the <u>Xilinx End User License</u>. The core is generated using the Xilinx ISE Embedded Edition software (EDK).

Performance

This section provides information about the performance of the AXI VDMA. Streaming side of AXI VDMA is looped back using shim logic. The block diagram shown in Figure 1-4 shows the configuration of the system that is used to report the frequency numbers in Table 1-1.

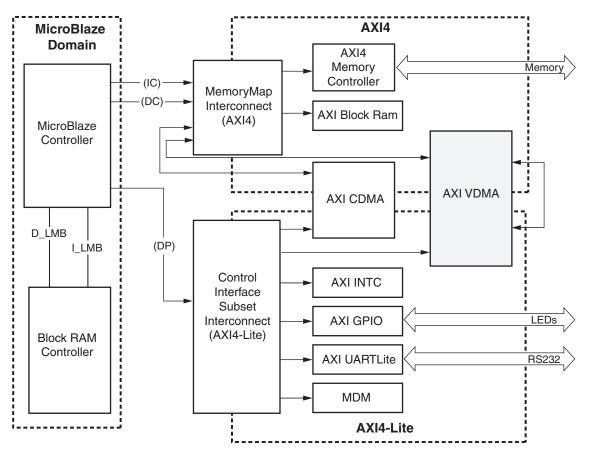

Figure 1-4: FPGA System Configuration Used for Generating System Performance Information

Maximum Frequencies

The target Field Programmable Gate Array (FPGA) was filled with logic to drive the Lookup Table (LUT) and block Random Access Memory (RAM) utilization to approximately 70% and the I/O utilization to approximately 80%. Using the default tool options and the slowest speed grade for the target FPGA, the resulting target FMAX numbers are shown in Table 1-1.

Fomily	Davias	Speed Crede	Fmax ⁽¹⁾								
Family	Device	Speed Grade	AXI4	AXI4-Lite	AXI4-Stream						
Spartan-6 ⁽²⁾	xc6slx45t	-2	150 MHz	100 MHz	150 MHz						
Virtex-6 ⁽³⁾	xc6vlx240t	-1	200 MHz	150 MHz	200 MHz						

Table 1-1: Maximum Frequencies

Notes:

1. Fmax numbers represent both MM2S and S2MM channel clocks.

2. In Spartan-6 system MicroBlaze freq is 80 MHz

3. In Virtex-6 system MicroBlaze freq is 150 MHz

Latency and Throughput

Table 1-2 and Table 1-3 describe the throughput and latency for the AXI VDMA. The tables provide performance information for a typical configuration. The throughput test consisted of eight video frames for each channel with each descriptor describing a 1000 lines at 1000 bytes per line per frame (~1 MByte) and each channel operating simultaneously (full duplex). Throughput is measured from completion of descriptor fetches (DMACR.Idle = 1) to frame count interrupt assertion. Latency is measured on both the mm2s and s2mm path. Table 1-3 shows the AXI VDMA core latency cycles only and does not include system dependent latency or throttling.

System Configuration

- AXI VDMA Configuration
 - $C_USE_FSYNC = 0$
 - C_NUM_FSTORES = 8
 - C_M_AXI_MM2S_DATA_WIDTH = 32 and C_M_AXI_S2MM_DATA_WIDTH = 32
 - C_M_AXIS_MM2S_TDATA_WIDTH = 32 and C_S_AXIS_S2MM_TDATA_WIDTH = 32
 - C_MM2S_MAX_BURST_LENGTH = 16 and C_S2MM_MAX_BURST_LENGTH = 16
 - C_MM2S_GENLOCK_MODE = 0 and C_S2MM_GENLOCK_MODE = 0
 - C_MM2S_LINEBUFFER_DEPTH = 0 and C_S2MM_LINEBUFFER_DEPTH = 0

Channel	Clock Frequency (in MHz)	Frame Size (In Bytes)	Maximum Total Data Throughput (MBytes/sec)	Percent of Theoretical
MM2S	80	1 MB	287	89.68
IVIIVI25	150	1 MB	539	89.83
S2MM Channel	80	1 MB	290	90.6
Szivilvi Charmer	150	1 MB	542	90.3

Table 1-2: AXI VDMA Throughput (Synchronous Mode)

Table 1-3: AXI VDMA Latency (Free Run Mode)

Description	Clocks
MM2S Channel	
mm2s_fsync_out to m_axi_mm2s_arvalid	14
m_axi_mm2s_rvalid to m_axis_mm2s_tvalid	4
last m_axis_mm2s_tlast to next mm2s_fsync_out	8
S2MM Channel	
s_axis_s2mm_tvalid to m_axi_s2mm_awvalid	14
m_axi_s2mm_awvalild = m_axi_s2mm_awready=1 to m_axi_s2mm_wvalid	2
last m_axi_s2mm_wlast to next s2mm_fsync_out	11

Resource Utilization

Resources required for the AXI VDMA core have been estimated for Virtex®-7, KintexTM-7, Virtex-6, and Spartan®-6 devices. These values were generated using the Xilinx 13.4 EDK tools. They are derived from post-synthesis reports and can change during MAP and PAR. Table 1-4 and Table 1-5 show 33 cases that are used for resource estimation.

Table 1-5 shows resource estimation for Virtex-7, Kintex-7, Virtex-6, and Spartan-6 devices for the 33 cases in Table 1-4 and Table 1-5.

Chapter 2

Core Interfaces and Register Space

This chapter describes the details for each interface. In addition, detailed information about configuration and control registers is included.

Port Descriptions

The AXI VDMA signals are described in Table 2-1.

Table 2-1: AXI VDMA I/O Signal Description

Signal Name	Interface	Signal Type	Init Status	Description
				AXI VDMA AXI4-Lite interface clock
s_axi_lite_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).
				AXI VDMA Scatter Gather clock
m_axi_sg_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).
				AXI VDMA MM2S clock
m_axi_mm2s_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).
				AXI VDMA S2MM clock
m_axi_s2mm_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).
				AXI VDMA MM2S AXIS clock
m_axis_mm2s_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).
				AXI VDMA S2MM AXIS clock
s_axis_s2mm_aclk	Clock	Ι		Note: All aclk inputs must be tied to the same clock source when AXI VDMA is configured for synchronous clock mode (C_PRMRY_IS_ACLK_ASYNC=0).

www.xilinx.com

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)
------------	--

Signal Name	Interface	Signal Type	Init Status	Description
axi_resetn	Reset	Ι		AXI VDMA Reset. Active-Low reset. When asserted low, resets entire AXI VDMA core. Must be synchronous to s_axi_lite_aclk and asserted for a minimum eight clock cycles.
mm2s_introut	Interrupt	Ο	0	Interrupt Out for Memory Map to Stream Channel
s2mm_introut	Interrupt	О	0	Interrupt Out for Stream to Memory Map Channel
	Video Syn	chroniza	ation Inte	erface Signals
mm2s_fsync	Frame Sync	I		MM2S Frame Sync Input. When enabled, VDMA Operations begin on each falling edge of fsync. This port is only valid when Use Frame Sync is enabled (C_USE_FSYNC=1).
mm2s_fsync_out	Frame Sync	О	0	MM2S Frame Sync Output. This signal asserts High for one m_axis_mm2s_aclk cycle with each frame boundary. This signals indicates to target video IP when a transfer of MM2S new frame data begins.
mm2s_prmtr_update	Frame Sync	0	0	MM2S Parameter Update. This signal indicates that new mm2s video parameters take effect on next frame. This signal is asserted for one m_axis_mm2s_aclk cycle coincident with mm2s_fsync_out.
s2mm_fsync	Frame Sync	I		S2MM Frame Sync Input. When enabled, VDMA operations begin on each falling edge of fsync. This port is only valid when Use Frame Sync is enabled (C_USE_FSYNC=1).
s2mm_fsync_out	Frame Sync	О	0	S2MM Frame Sync Output. This signal asserts High for one s_axis_s2mm_aclk cycle with each frame boundary. Indicates when S2MM new frame data can be transferred to the S2MM channel by video IP.
s2mm_prmtr_update	Frame Sync	0	0	S2MM Parameter Update. This signal indicates that new s2mm video parameters take effect on next frame. This signal is asserted for one s_axis_s2mm_aclk cycle coincident with s2mm_fsync_out.
	Ge	nlock In	terface S	bignals
mm2s_frame_ptr_in((C_ MM2S_GENLOCK_NUM_ MASTERS*6)-1: 0)	Genlock	I		MM2S Frame Pointer Input. In Genlock Slave mode, specifies the next frame for MM2S to operate on.
mm2s_frame_ptr_out(5:0)	Genlock	Ο	zeros	MM2S Frame Pointer Output. In Genlock Master mode, specifies the next frame for the slave VDMA to operate on.
s2mm_frame_ptr_in((C_ S2MM_GENLOCK_NUM_ MASTERS*6)-1: 0)	Genlock	I		S2MM Frame Pointer Input. In Genlock Slave mode, specifies the next frame for S2MM to operate on.

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)	
------------	--	--

Signal Name	Interface	Signal Type	Init Status	Description							
s2mm_frame_ptr_out(5:0)	Genlock	Ο	zeros	S2MM Frame Pointer Output. In Genlock Master mode, specifies the next frame for the slave VDMA to operate on.							
Line Buffer interface Signals											
mm2s_buffer_empty	LineBuffer	Ο	1	MM2S Line Buffer Empty. Indicates that the MM2S line buffer contains no stored data elements.							
mm2s_buffer_almost_empty	LineBuffer	О	1	MM2S Line Buffer Almost Empty. Indicates that the MM2S line buffer has MM2S_FRMSTORE bytes or less stored. When mm2s_buffer_empty asserts, mm2s_buffer_almost_empty remains asserted.							
s2mm_buffer_full	LineBuffer	0	0	S2MM Line Buffer Full. Indicates that the S2MM line buffer has no more room to store data elements.							
s2mm_buffer_almost_full	LineBuffer	О	0	S2MM Line Buffer Almost Full. Indicates that the S2MM line buffer has S2MM_FRMSTORE bytes or more. When s2mm_buffer_full asserts, s2mm_buffer_almost_full remains asserted.							
	AXI	4-Lite In	terface S	Signals							
s_axi_lite_awvalid	S_AXI_LITE	Ι		 AXI4-Lite Write Address Channel Write Address Valid. 1 = Write address is valid. 0 = Write address is not valid. 							
s_axi_lite_awready	S_AXI_LITE	0	0	 AXI4-Lite Write Address Channel Write Address Ready. Indicates that DMA is ready to accept the write address. 1 = Ready to accept address. 0 = Not ready to accept address. 							
s_axi_lite_awaddr(31:0)	S_AXI_LITE	Ι		AXI4-Lite Write Address Bus.							
s_axi_lite_wvalid	S_AXI_LITE	Ι		 AXI4-Lite Write Data Channel Write Data Valid. 1 = Write data is valid. 0 = Write data is not valid. 							
s_axi_lite_wready	S_AXI_LITE	0	0	 AXI4-Lite Write Data Channel Write Data Ready. Indicates DMA is ready to accept the write data. 1 = Ready to accept data. 0 = Not ready to accept data. 							
s_axi_lite_wdata(31:0)	S_AXI_LITE	Ι		AXI4-Lite Write Data Bus.							

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)
------------	--

Signal Name	Interface	Signal Type	Init Status	Description
s_axi_lite_bresp(1:0)	S_AXI_LITE	0	Don't care	 AXI4-Lite Write Response Channel. Indicates results of the write transfer. The AXI VDMA Lite interface always responds with OKAY. 00b = OKAY - Normal access has been successful. 01b = EXOKAY - Not supported. 10b = SLVERR - Not supported. 11b = DECERR - Not supported.
s_axi_lite_bvalid	S_AXI_LITE	0	0	 AXI4-Lite Write Response Channel Response Valid. Indicates response is valid. 1 = Response is valid. 0 = Response is not valid.
s_axi_lite_bready	S_AXI_LITE	Ι		 AXI4-Lite Write Response Channel Ready. Indicates target is ready to receive response. 1 = Ready to receive response. 0 = Not ready to receive response.
s_axi_lite_arvalid	S_AXI_LITE	Ι		 AXI4-Lite Read Address Channel Read Address Valid. 1 = Read address is valid. 0 = Read address is not valid.
s_axi_lite_arready	S_AXI_LITE	Ο	0	 AXI4-Lite Read Address Channel Read Address Ready. Indicates DMA is ready to accept the read address. 1 = Ready to accept address. 0 = Not ready to accept address.
s_axi_lite_araddr(31:0)	S_AXI_LITE	Ι		AXI4-Lite Read Address Bus.
s_axi_lite_rvalid	S_AXI_LITE	0	0	 AXI4-Lite Read Data Channel Read Data Valid. 1 = Read data is valid. 0 = Read data is not valid.
s_axi_lite_rready	S_AXI_LITE	Ι		 AXI4-Lite Read Data Channel Read Data Ready. Indicates target is ready to accept the read data. 1 = Ready to accept data. 0 = Not ready to accept data.
s_axi_lite_rdata(31:0)	S_AXI_LITE	0	Don't	AXI4-Lite Read Data Bus
s_axi_lite_rresp(1:0)	S_AXI_LITE	0	Don't care	 AXI4-Lite Read Response Channel Response. Indicates results of the read transfer. The AXI VDMA Lite interface always responds with OKAY. 00b = OKAY - Normal access has been successful. 01b = EXOKAY - Not supported. 10b = SLVERR - Not supported. 11b = DECERR - Not supported.

Table 2-1: AXI VDMA I/O Signal Description (Cont'd)

Signal Name	Interface	Signal Type	Init Status	Description
	MM2S Mem	ory Map	Read In	terface Signals
m_axi_mm2s_araddr (C_M_AXI_MM2S_ADDR_ WIDTH-1: 0)	M_AXI_MM2S	0	Don't care	Read Address Channel Address Bus
m_axi_mm2s_arlen(7:0)	M_AXI_MM2S	0	Don't care	Read Address Channel Burst Length. In data beats - 1.
m_axi_mm2s_arsize(2:0)	M_AXI_MM2S	0	Don't care	 Read Address Channel Burst Size. Indicates width of burst transfer. 000b = 1 byte (8-bit wide burst). 001b = 2 bytes (16-bit wide burst). 010b = 4 bytes (32-bit wide burst). 011b = 8 bytes (64-bit wide burst). 100b = 16 bytes (128-bit wide burst). 101b = 32 bytes (256-bit wide burst). 110b = 64 bytes (512 bit wide burst). 111b = 128 bytes (1024 bit wide burst).
m_axi_mm2s_arburst(1:0)	M_AXI_MM2S	О	Don't care	 Read Address Channel Burst Type. Indicates type burst. 00b = FIXED - Not supported. 01b = INCR - Incrementing address. 10b = WRAP - Not supported. 11b = Reserved.
m_axi_mm2s_arprot(2:0)	M_AXI_MM2S	0	000b	Read Address Channel Protection. Always driven with a constant output of 000b along with m_axi_mm2s_arvalid.
m_axi_mm2s_arcache(3:0)	M_AXI_MM2S	0	0011b	Read Address Channel Cache. Always driven with a constant output of 0011b along with m_axi_mm2s_arvalid.
m_axi_mm2s_arvalid	M_AXI_MM2S	0	0	 Read Address Channel Read Address Valid. Indicates m_axi_mm2s_araddr is valid. 1 = Read address is valid. 0 = Read address is not valid.
m_axi_mm2s_arready	M_AXI_MM2S	I		 Read Address Channel Read Address Ready. Indicates target is ready to accept the read address. 1 = Target read to accept address. 0 = Target not ready to accept address.
m_axi_mm2s_rdata (C_M_AXI_MM2S_DATA_ WIDTH-1: 0)	M_AXI_MM2S	Ι		Read Data Channel Read Data.

Table 2-1: AXI VDMA I/O Signal Description (Cont'd)

Signal Name	Interface	Signal Type	Init Status	Description
m_axi_mm2s_rresp(1:0)	M_AXI_MM2S	I		 Read Data Channel Response. Indicates results of the read transfer. 00b = OKAY - Normal access has been successful. 01b = EXOKAY - Not supported. 10b = SLVERR - Slave returned error on transfer. 11b = DECERR - Decode error, transfer targeted unmapped address.
m_axi_mm2s_rlast	M_AXI_MM2S	Ι		 Read Data Channel Last. Indicates the last data beat of a burst transfer. 1 = Last data beat. 0 = Not last data beat.
m_axi_mm2s_rvalid	M_AXI_MM2S	Ι		 Read Data Channel Data Valid. Indicates m_axi_mm2s_rdata is valid. 1 = Valid read data. 0 = Not valid read data.
m_axi_mm2s_rready	M_AXI_MM2S	0		 Read Data Channel Ready. Indicates the read channel is ready to accept read data. 1 = Ready. 0 = Not ready.
	MM2S Ma	ster Stre	eam Inte	rface Signals
mm2s_prmry_reset_out_n	M_AXIS_MM2S	0	0	Primary MM2S Reset Out.
m_axis_mm2s_tdata (C_M_AXIS_MM2S_TDATA _WIDTH-1: 0)	M_AXIS_MM2S	О	Don't care	AXI4-Stream Data Out.
m_axis_mm2s_tkeep (C_M_AXIS_MM2S_TDATA _WIDTH/8-1: 0)	M_AXIS_MM2S	О	Don't care	 AXI4-Stream Write Keep. Indicates valid bytes on stream data. (For most use cases, all bytes will be valid.) 1 = Byte is valid 0 = Byte is not valid
m_axis_mm2s_tuser[C_M_ AXIS_MM2S_TUSER_BITS- 1:0]	M_AXIS_MM2S	0	Don't care	AXI4-Stream user bits. tuser(0) drives out mm2s start of frame (SOF).
m_axis_mm2s_tvalid	M_AXIS_MM2S	О	0	 AXI4-Stream Valid Out. Indicates stream data bus, m_axis_mm2s_tdata, is valid 1 = Write data is valid. 0 = Write data is not valid.
m_axis_mm2s_tready	M_AXIS_MM2S	Ι		 AXI4-Stream Ready. Indicates to S2MM channel target is ready to receive stream data. 1 = Ready to receive data. 0 = Not ready to receive data.

Table 2-1:	AXI VDMA I/C	Signal Description	(Cont'd)
------------	--------------	--------------------	----------

Signal Name	Interface	Signal Type	Init Status	Description
m_axis_mm2s_tlast	M_AXIS_MM2S	О	Don't care	 AXI4-Stream Last. Indicates last data beat of stream data. 1 = Last data beat. 0 = Not last data beat.
	S2MM Mem	ory Map	Write In	terface Signals
m_axi_s2mm_awaddr (C_M_AXI_S2MM_ADDR_ WIDTH-1: 0)	M_AXI_S2MM	О	Don't care	Write Address Channel Address Bus.
m_axi_s2mm_awlen(7:0)	M_AXI_S2MM	0	Don't care	Write Address Channel Burst Length. In data beats - 1.
m_axi_s2mm_awsize(2: 0)	M_AXI_S2MM	0	Don't care	 Write Address Channel Burst Size. Indicates width of burst transfer. 000b = 1 byte (8 bit wide burst). 001b = 2 bytes (16 bit wide burst). 010b = 4 bytes (32 bit wide burst). 011b = 8 bytes (64 bit wide burst). 100b = 16 bytes (128 bit wide burst). 101b = 32 bytes (256 bit wide burst). 110b = 64 bytes (512 bit wide burst). 111b = 128 bytes (1024 bit wide burst).
m_axi_s2mm_awburst(1:0)	M_AXI_S2MM	0	Don't care	 Write Address Channel Burst Type. Indicates type burst. 00b = FIXED - Not supported. 01b = INCR - Incrementing address. 10b = WRAP - Not supported. 11b = Reserved.
m_axi_s2mm_awprot(2:0)	M_AXI_S2MM	0	000b	Write Address Channel Protection. Always driven with a constant output of 000b along with m_axi_s2mm_awvalid.
m_axi_s2mm_awcache(3:0)	M_AXI_S2MM	0	0011b	Write Address Channel Cache. Always driven with a constant output of 0011b along with m_axi_s2mm_awvalid.
m_axi_s2mm_awvalid	M_AXI_S2MM	0	0	 Write Address Channel Write Address Valid. Indicates if m_axi_s2mm_awaddr is valid. 1 = Write Address is valid. 0 = Write Address is not valid.
m_axi_s2mm_awready	M_AXI_S2MM	Ι		 Write Address Channel Write Address Ready. Indicates target is ready to accept the write address. 1 = Target read to accept address. 0 = Target not ready to accept address.
m_axi_s2mm_wdata (C_M_AXI_S2MM_DATA_ WIDTH-1: 0)	M_AXI_S2MM	О	Don't care	Write Data Channel Write Data Bus.

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)
------------	--

Signal Name	Interface	Signal Type	Init Status	Description
m_axi_s2mm_wstrb (C_M_AXI_S2MM_DATA_ WIDTH/8 - 1: 0)	M_AXI_S2MM	О	Don't care	Write Data Channel Write Strobe Bus. Indicates which bytes are valid in the write data bus. This value is passed from the stream side strobe bus.
m_axi_s2mm_wlast	M_AXI_S2MM	0	Don't care	 Write Data Channel Last. Indicates the last data beat of a burst transfer. 1 = Last data beat. 0 = Not last data beat.
m_axi_s2mm_wvalid	M_AXI_S2MM	0	0	 Write Data Channel Data Valid. Indicates m_axi_s2mm_wdata is valid. 1 = Valid write data. 0 = Not valid write data.
m_axi_s2mm_wready	M_AXI_S2MM	Ι		 Write Data Channel Ready. Indicates the write channel target is ready to accept write data. 1 = Target is ready 0 = Target is not ready
m_axi_s2mm_bresp(1:0)	M_AXI_S2MM	I		 Write Response Channel Response. Indicates results of the write transfer. 00b = OKAY - Normal access has been successful. 01b = EXOKAY - Not supported. 10b = SLVERR - Slave returned error on transfer. 11b = DECERR - Decode error, transfer targeted unmapped address.
m_axi_s2mm_bvalid	M_AXI_S2MM	I		 Write Response Channel Response Valid. Indicates response, m_axi_s2mm_bresp, is valid. 1 = Response is valid. 0 = Response is not valid.
m_axi_s2mm_bready	M_AXI_S2MM	0	0	 Write Response Channel Ready. Indicates MM2S write channel is ready to receive response. 1 = Ready to receive response. 0 = Not ready to receive response.

Table 2-1: AXI VDMA I/O Signal Description (Cont'd)

Signal Name	Interface	Signal Type	Description	
	S2MM SI	ave Stre	am Inter	face Signals
s2mm_prmry_reset_out_n	M_AXIS_S2MM	0	Ο	Primary S2MM Reset Out
s_axis_s2mm_tdata (C_S_AXIS_S2MM_TDATA_ WIDTH-1: 0)	S_AXIS_S2MM	Ι		AXI4-Stream Data In
s_axis_s2mm_tkeep (C_S_AXIS_S2MM_TDATA_ WIDTH/8-1: 0)	S_AXIS_S2MM	Ι		 AXI4-Stream Write Keep. Indicates valid bytes on stream data. (For most use cases, all bytes are valid.). It needs to be tied High if stream master does not have this signal. 1 = Byte is valid 0 = Byte is not valid
s_axis_s2mm_tuser[C_S_ AXIS_S2MM_TUSER_BITS- 1:0]	M_AXIS_S2MM	О	Don't care	AXI4-Stream user bits. The signal tuser(0) receives in s2mm start of frame (SOF).
s_axis_s2mm_tvalid	S_AXIS_S2MM	Ι		 AXI4-Stream Valid In. Indicates stream data bus, s_axis_s2mm_tdata, is valid. 1 = Write data is valid. 0 = Write data is not valid.
s_axis_s2mm_tready	S_AXIS_S2MM	0	0	 AXI4-Stream Ready. Indicates MM2S channel stream interface ready to receive stream data. 1 = Ready to receive data. 0 = Not ready to receive data.
s_axis_s2mm_tlast	S_AXIS_S2MM	Ι		 AXI4-Stream Last. Indicates last data beat of stream data. 1 = Last data beat. 0 = Not last data beat.
	Scatter Gather	lemory	Map Rea	ad Interface Signals
m_axi_sg_araddr (C_M_AXI_SG_ADDR_ WIDTH-1: 0)	M_AXI_SG	0	Don't care	Scatter Gather Read Address Channel Address Bus.
m_axi_sg_arlen(7:0)	M_AXI_SG	О	Don't care	Scatter Gather Read Address Channel Burst Length. Length in data beats - 1.
m_axi_sg_arsize(2: 0)	M_AXI_SG	0	Don't care	 Scatter Gather Read Address Channel Burst Size. Indicates with of burst transfer. 000b = Not Supported by AXI VDMA SG Engine. 001b = Not Supported by AXI VDMA SG Engine. 010b = 4 bytes (32 bit wide burst). 011b = Not Supported by AXI VDMA SG Engine. 100b = Not Supported by AXI VDMA SG Engine. 100b = Not Supported by AXI VDMA SG Engine. 101b = Not Supported by AXI VDMA SG Engine. 110b = Not Supported by AXI VDMA SG Engine. 110b = Not Supported by AXI VDMA SG Engine. 110b = Not Supported by AXI VDMA SG Engine. 110b = Not Supported by AXI VDMA SG Engine.

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)
------------	--

Signal Name	Interface	Signal Type	Init Status	Description
m_axi_sg_arburst(1:0)	M_AXI_SG	0	Don't care	 Scatter Gather Read Address Channel Burst Type. Indicates type burst. 00b = FIXED - Not supported. 01b = INCR - Incrementing address. 10b = WRAP - Not supported. 11b = Reserved.
m_axi_sg_arprot(2:0)	M_AXI_SG	0	000b	Scatter Gather Read Address Channel Protection. Always driven with a constant output of 000b along with m_axi_sg_arvalid.
m_axi_sg_arcache(3:0)	M_AXI_SG	0	0011b	Scatter Gather Read Address Channel Cache. Always driven with a constant output of 0011b along with m_axi_sg_arvalid.
m_axi_sg_arvalid	M_AXI_SG	0	0	 Scatter Gather Read Address Channel Read Address Valid. Indicates if m_axi_sg_araddr is valid. 1 = Read Address is valid. 0 = Read Address is not valid.
m_axi_sg_arready	M_AXI_SG	I		 Scatter Gather Read Address Channel Read Address Ready. Indicates target is ready to accept the read address. 1 = Target read to accept address. 0 = Target not ready to accept address.
m_axi_sg_rdata (C_M_AXI_SG_DATA_ WIDTH-1: 0)	M_AXI_SG	Ι		Scatter Gather Read Data Channel Read Data.
m_axi_sg_rresp(1:0)	M_AXI_SG	I		 Scatter Gather Read Data Channel Response. Indicates results of the read transfer. 00b = OKAY - Normal access has been successful. 01b = EXOKAY - Not supported. 10b = SLVERR - Slave returned error on transfer. 11b = DECERR - Decode error, transfer targeted unmapped address.
m_axi_sg_rlast	M_AXI_SG	I		 Scatter Gather Read Data Channel Last. Indicates the last data beat of a burst transfer. 1 = Last data beat. 0 = Not last data beat.

Table 2-1:	AXI VDMA I/O Signal Description (Cont'd)
------------	--

Signal Name	Interface	Signal Type	Init Status	Description		
m_axi_sg_rdata	M_AXI_SG	Ι		 Scatter Gather Read Data Channel Data Valid. Indicates m_sg_aximry_rdata is valid. 1 = Valid read data. 0 = Not valid read data. 		
m_axi_sg_rready	M_AXI_SG	0	0	 Scatter Gather Read Data Channel Ready. Indicates the read channel is ready to accept read data. 1 = Is ready. 0 = Is not ready. 		

Parameter – I/O Signal Dependencies

 Table 2-2:
 Parameter – I/O Signal Dependencies

Parameter Name	Affects Signal	Relationship Description
C_M_AXI_SG_DATA_WIDTH	m_axi_sg_rdata	The setting of the parameter sets the vector width of the port.

Table 2-2: Parameter – I/O Signal Dependencies (Cont'd)

Register Space

The AXI VDMA core register space for Register Direct mode is shown in Table 2-3 and for Scatter Gather Mode is shown in Table 2-4. The AXI VDMA Registers are memory-mapped into non-cacheable memory space. This memory space must be aligned on a AXI word (32-bit) boundary.

Endianess

All registers are in Little Endian format, as shown in Figure 2-1.

MSE	3										LSB
	Addr Offset 0x03			Addr Offset 0x02			Addr Offset 0x01			Addr Offset 0x00	
31	BYTE3	24	23	BYTE2	16	15	BYTE 1	8	7	BYTE 0	0

S2MM_START_ADDRESS12 ^{(2) (3)}	S2MM Start Address 12	D8h
S2MM_START_ADDRESS13 ^{(2) (3)}	S2MM Start Address 13	DCh
S2MM_START_ADDRESS14 ⁽²⁾⁽³⁾	S2MM Start Address 14	E0h

Name	Description	Address Space Offset (1)
S2MM_START_ADDRESS15 ^{(2) (3)}	S2MM Start Address 15	E4h
S2MM_START_ADDRESS16 ^{(2) (3)}	S2MM Start Address 16	E8h

1. Address Space Offset is relative to C_BASEADDR assignment.

2. Start Addresses 2 to 32 for MM2S and S2MM depend on C_NUM_FSTORES parameter. Start address registers greater than C_NUM_FSTORES setting are reserved. Only MM2S_FRMSTORE or S2MM_FRMSTORE start address registers for the respective channel are used for transfers. See the MM2S_REG_INDEX and S2MM_REG_INDEX register definitions for accessing 32 start address registers.

3. Video parameter and start address registers are Read/Writable when the video parameter reads are enabled. (C_ENABLE_VIDPRMTR_READS=1) and are Write Only when the video parameter reads are disabled. (C_ENABLE_VIDPRMTR_READS=0).

AXI VDMA Register Address Mapping For Scatter Gather Mode

Name	Description	Address Space Offset ^a

S2MM_THRESHOLD	S2MM Line Buffer Threshold Register	4Ch

Table 2-4: Register Address Mapping for Scatter Gather Mode

a. Address Space Offset is relative to C_BASEADDR assignment. C_BASEADDR is defined in AXI VDMA mpd file and set by XPS.

Memory Map to Stream Register Detail

MM2S_DMACR (MM2S DMA Control Register – Offset 00h) (C_INCLUDE_SG = 1/0)

This register provides control for the Memory Map to Stream DMA Channel for both Scatter Gather mode and Register Direct mode.

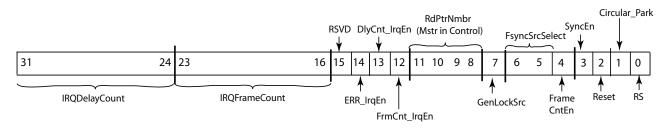

Figure 2-2: MM2S DMACR Register

Table 2-5:	MM2S_	DMACR	Register	Details
------------	-------	-------	----------	---------

Bits	Field Name	Default Value	Access Type	Description
31 downto 24	IRQDelayCount	00h	R/W	This value is used for setting the interrupt delay count value. The delay count interrupt is a mechanism for causing the DMA engine to generate an interrupt after the delay period has expired. This is used for cases when the interrupt frame count is not met after a period of time and the CPU desires an interrupt to be generated. Timer begins counting at the start of a frame and resets with the transfer of a new packet on MM2S stream or when delay count period has expired. When a value different than the current IRQDelayCount is written to this field, the internal delay counter is reset to zero.
				Setting this value to zero disables the delay counter interrupt.
23 downto 16	IRQFrameCount	01h R/W	This value is used for setting the interrupt threshold. When frame transfer interrupt events occur, an internal counter counts down from the Interrupt Frame Count setting. When the count reaches zero, an interrupt out is generated by the VDMA engine. When a value different than the current IRQFrameCount is written to this field, the internal frame counter is reset to the new value. The minimum setting for the count is 0x01. A write of 0x00 to this register set the count to 0x01	
				this register sets the count to 0x01. When DMACR.FrameCntEn = 1, this value determines the
				number of frame buffers to process.
15	Reserved	0	RO	Writing to this bit has no effect and it is always read as zeros.
14 Err_Irq	Err_IrqEn	0	R/W	Interrupt on Error Interrupt Enable. When set to 1, allows DMASR.Err_Irq to generate an interrupt out. 0 = Error Interrupt disabled
				1 = Error Interrupt enabled

www.xilinx.com

Bits	Field Name	Default Value	Access Type	Description
13	DlyCnt_IrqEn	0	R/W	Interrupt on Delay Count Interrupt Enable. When set to 1, allows DMASR.DlyCnt_Irq to generate an interrupt out. 0 = Delay Count Interrupt disabled 1 = Delay Count Interrupt enabled
12	FrmCnt_IrqEn	0	R/W	Frame Count Complete Interrupt Enable. When set to 1, allows DMASR.FrmCnt_Irq to generate an interrupt out when IRQFrameCount value reaches zero. 0 = Frame Count Interrupt disabled 1 = Frame Count Interrupt enabled
				Indicates the master in control when MM2S channel is configured for Genlock slave mode (C_MM2S_GENLOCK_MODE = 1). 0000b = Controlling master is Master 1 0001b = Controller master is Master 2
11 downto 8 RdPntrNum zeros	R/W	00010 = Controller master is Master 2 0010b = Controller master is Master 3 and so on. Maximum valid RdPntrNum is C_MM2S_GENLOCK_NUM_MASTER - 1. Setting to a value greater than C_MM2S_GENLOCK_NUM_MASTER - 1 has undefined results.		
7	Genlock Source	0	R/W	 Sets the Genlock source for Genlock slaves. 0 = External Genlock 1 = Internal Genlock
6 downto 5	FsyncSrcSelect	00	R/W	 Selects the frame sync source for the MM2S channel. The frame sync source is selected as follows: 00 = mm2s_fsync 01 = s2mm_fsync 10 = reserved 11 = reserved Note: Frame Sync Source Select is only valid if configured for external frame sync (C_USE_FSYNC = 1).
4	FrameCntEn	0	R/W	Configures the MM2S channel to allow only IRQFrameCount number of transfers to occur. After IRQFrameCount frames have been transferred, the MM2S channel halts, DMACR.RS bit is cleared to 0, and DMASR.Halted asserts to 1 when the channel has completely halted.

Table 2-5: MM2S_DMACR Register Details (Cont'd)

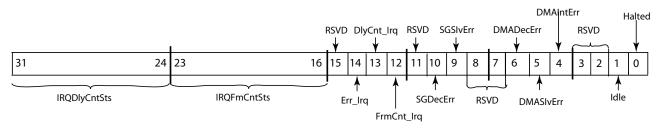

Bits	Field Name	Default Value	Access Type	Description
				Enables Genlock synchronization.
				0 = Genlock synchronization disabled. Genlock input is ignored by MM2S.
3	SyncEn	0	R/W	1 = Genlock synchronization enabled. MM2S synchronized to Genlock frame input.
				Note: This value is only valid when the channel is configured as Genlock Slave (C_MM2S_GENLOCK_MODE = 1). If configured for Genlock Master mode (C_MM2S_GENLOCK_MODE = 0), this bit is reserved and always reads as zero.
2	Reset	0	R/W	Soft reset for resetting the AXI VDMA MM2S channel. Setting this bit to a 1 causes the AXI VDMA MM2S channel to be reset. Reset is accomplished gracefully. Pending commands/transfers are flushed or completed. AXI4-Stream reset output is asserted. Setting DMACR.Reset = 1 only resets the MM2S channel. After completion of a soft reset all MM2S registers and bits are in the Reset State. 0 = Reset NOT in progress – Normal operation
				1 = Reset in progress
				Indicates frame buffer Circular mode or frame buffer Park mode.
1	Circular_Park	1	R/W	0 = Park Mode— Engine will park on frame buffer referenced by PARK_PTR_REG.RdFrmPntrRef.
				1 = Circular Mode – Engine continuously circles through MM2S_FRMSTORE frame buffers.
				Run / Stop controls running and stopping of the VDMA channel. For any DMA operations to commence, the AXI VDMA engine must be running (DMACR.RS=1).
0	RS	0	R/W	0 = Stop – VDMA stops when current (if any) DMA operations are complete. Queued descriptors for the associated channel are flushed from the SG Engine. The halted bit in the DMA Status Register asserts to 1 when the DMA engine is halted. This bit gets cleared by AXI VDMA hardware when an error occurs or when the IRQFrameCount is reached when Frame Count Enable is asserted (DMACR.FrameCntEn = 1). The CPU can also choose to clear this bit to stop DMA operations.
				1 = Run — Start DMA operations. The halted bit in the DMA Status Register deasserts to 0 when the DMA engine begins operations.
				Note: On Run/Stop clear, in-progress stream transfers might terminate early.
RO = Read On	⊥ ly. Writing has no ef	fect.	I	

Table 2-5:	MM2S_	DMACR	Register	Details	(Cont'd)
------------	-------	-------	----------	---------	----------

R/W = Read / Write.

MM2S_DMASR (MM2S DMA Status Register – Offset 04h) (C_INCLUDE_SG = 1/0)

This register provides the status for the Memory Map to Stream DMA Channel for both Scatter Gather mode and Register Direct mode.

Bits	Field Name	Default Value	Access Type	Description
31 downto 24	IRQDelayCntSts	00h	RO	Interrupt Delay Count Status. Indicates current interrupt delay time value.
23 downto 16	IRQFrameCntSts	01h	RO	Interrupt Frame Count Status. Indicates current interrupt frame count value.
15	Reserved	0	RO	Always read as zero.
14	Err_Irq	0	R/WCInterrupt on Error. When set to 1, indicates an interrupt of was generated on error. If enabled (DMACR.Err_IrqEn = interrupt out is generated from the AXI VDMA. 0 = No error Interrupt. 1 = Error interrupt detected.	
13	DlyCnt_Irq	0	R/WC	 Interrupt on Delay. Delay counter begins counting at the beginning of each frame and resets at delay count or transfer of video line. If delay count is reached, the bit sets to 1, indicating an interrupt event was generated due to delay counter. If enabled (DMACR.DlyCnt_IrqEn = 1), an interrupt out is generated from the AXI VDMA. 0 = No Delay Interrupt. 1 = Delay Interrupt detected.
12	FrmCnt_Irq	0	R/WC	 Frame Count Interrupt. When set to 1, indicates a Frame Count interrupt event was generated. This occurs when DMACR.FrameCount frames have been transferred. If enabled (DMACR.FrmCnt_IrqEn = 1) and if the interrupt threshold has been met, an interrupt out is generated from the AXI VDMA. 0 = No Frame Count Interrupt. 1 = Frame Count Interrupt detected.
11	Reserved	0	RO	Writing to this bit has no effect, and it is always read as zeros.

Table 2-6: MM2S_DMASR Register Details

www.xilinx.com

Bits	Field Name	Default Value	Access Type	Description
				Scatter Gather Decode Error. In Scatter Gather Mode (C_INCLUDE_SG =1) this bit indicates a Decode Error was detected by the Scatter Gather Engine. This error occurs if the address request is to an invalid address (that is, CURDESC and/ or NXTDESC points to an invalid address). This error condition causes both AXI VDMA channels (MM2S and S2MM) to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1 for both channels.
10	SGDecErr	0	RO	For Register Direct Mode (C_INCLUDE_SG = 0) this bit is reserved and always read as $0b$.
				• 0 = No SG Decode Errors.
				• 1 = SG Decode Error detected. DMA Engine halts.
				Note: In Scatter / Gather Mode (C_INCLUDE_SG = 1) the CURDESC register is updated with the errored descriptor pointer when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one address is updated to the CURDESC. A reset (soft or hard) must be issued to clear the error condition.
				<i>Note:</i> On Error, in-progress stream transfers might terminate early.
				Scatter Gather Slave Error. In Scatter Gather Mode (C_INCLUDE_SG =1) this bit indicates a Slave Error was detected by the Scatter Gather Engine. This error occurs if the slave read from on the Memory Map interface issues a Slave error. This error condition causes both AXI VDMA channels (MM2S and S2MM) to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1 for both channels. For Register Direct Mode (C_INCLUDE_SG = 0) this bit is
9	SGSlvErr	0	RO	reserved and always read as 0b.
·		_		• 0 = No SG Slave Errors.
				• 1 = SG Slave Error detected. DMA Engine halts.
		Note: In Scatter Gather Mode (C_INCLUDE_SG = 1) the CURDESC register is updated with the errored descriptor pointer when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one address is updated to the CURDESC. A reset (soft or hard) must be issued to clear the error condition.		
				<i>Note:</i> On Error, in-progress stream transfers might terminate early.
8 downto 7	Reserved	zeros	RO	Writing to these bits has no effect, and they are always read as zeros.

Table 2-6:	MM2S	DMASR	Register	Details	(Cont'd)
------------	------	-------	----------	---------	----------

Bits	Field Name	Default Value	Access Type	Description
				DMA Decode Error. Decode error detected by primary AXI DataMover. This error occurs if the address request is to an invalid address.
				For Scatter Gather Mode (C_INCLUDE_SG = 1) this situation can happen if the Descriptor Buffer Address points to an invalid address.
				For Register Direct Mode (C_INCLUDE_SG = 0) this situation can happen if the Start Address/es point to an invalid address.
6	DMADecErr	0	RO	This error condition causes the AXI VDMA MM2S channel to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1.
				• 0 = No DMA Decode Errors.
				• 1 = DMA Decode Error detected. DMA channel halts.
				Note: The PRK_PTR_REG.RdFrmStore field is updated with the errored frame reference when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.RdFrmStore. A reset (soft or hard) must be issued to clear the error condition.
				Note: On Error, in-progress stream transfers might terminate early.
				DMA Slave Error. Slave error detected by primary AXI DataMover. This error occurs if the slave read from the Memory Map interface issues a Slave Error. This error condition causes the AXI VDMA MM2S channel to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1.
5	DMASlvErr	0	RO	 0 = No DMA Slave Errors. 1 DMA Slave Error detected DMA Errors helts
			 1 = DMA Slave Error detected. DMA Engine halts. <i>Note:</i> The PRK_PTR_REG.RdFrmStore field is updated with the errored frame reference when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.RdFrmStore. A reset (soft or hard) must be issued to clear the error condition. <i>Note:</i> On error, in-progress stream transfers might terminate early. 	

Bits	Field Name	Default Value	Access Type	Description
				DMA Internal Error. Internal error detected by primary AXI DataMover. This error can occur if a 0 length bytes to transfer is fed to the AXI DataMover.
				For Scatter Gather Mode this situation can happen if the vertical size (vsize) and/or the horizontal size (hsize) specified in the fetched descriptor is set to 0.
				For Register Direct Mode (C_INCLUDE_SG = 0) this situation can happen if the vertical size (vsize) and/or the horizontal size (hsize) specified in MM2S_VSIZE and MM2S_HSIZE respectively is set to 0 when MM2S_VSIZE is written.
				This error condition causes the AXI VDMA MM2S channel to halt gracefully. The DMACR.RS bit is set to 0, and when the channel has completely shut down, the DMASR.Halted bit is set
4	DMAIntErr	0	RO	to 1.
				 0 = No DMA Internal Errors. 1 DMA Internal Errors detected DMA showed halfs
				• 1 = DMA Internal Error detected. DMA channel halts.
				This error can also occur if a packet greater or less than hsize bytes is received. If the external frame sync is enabled (C_USE_FSYNC=1) and Flush On Frame Sync is enabled (C_FLUSH_ON_FSYNC = 1), then on the next frame sync the channel is flushed, reset, and DMA processing begins again.
				Note: The PRK_PTR_REG.RdFrmStore field is updated with the errored frame reference when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.RdFrmStore. A reset (soft or hard) must be issued to clear the error condition.
				Note: On error, in-progress stream transfers might terminate early.
3 downto 2	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
				DMA Scatter Gather Engine Idle. In Scatter Gather Mode (C_INCLUDE_SG = 1) this bit indicates the state of AXI VDMA Scatter Gather Engine operations. The assertion of Idle indicates the SG Engine has reached the tail pointer for the associated channel and all queued descriptors have been processed. If in the Idle state (DMASR.Idle = 1), writing to the TailPointer register automatically restarts DMA operations.
1	Idle	0	RO	For Register Direct Mode (C_INCLUDE_SG = 0) this bit is reserved and always read as $0b$.
				 0 = Not Idle - SG operations for MM2S channel in progress. 1 = Idle - SG operation for MM2S channel paused.
				Note: DMASR.Idle only asserts after the SG engine has passed through the descriptor chain at least once and has reached the TAILDESC.
				Note: Writing to the TAILDESC register when not Idle (DMASR.Idle = 0) produces undefined results.

Table 2-6:	MM2S	_DMASR	Register	Details	(Cont'd)
------------	------	--------	----------	---------	----------

Table 2-6:	MM2S	_DMASR	Register	Details	(Cont'd)
------------	------	--------	----------	---------	----------

Bits	Field Name	Default Value	Access Type	Description
0	Halted	1	RO	 DMA Channel Halted. DMA Channel Halted. Indicates the run/ stop state of the DMA channel. 0 = DMA channel running 1 = DMA channel halted. This bit gets set when DMACR.RS = 0 and DMA and SG operations have halted. There can be a lag of time between when DMACR.RS = 0 and when DMASR.Halted = 1. Note: When halted (RS= 0 and Halted = 1), writing to CURDESC or TAILDESC pointer registers in Scatter Gather mode (C_INCLUDE_SG = 1) or Register Direct Mode (C_INCLUDE_SG = 0) has no effect on DMA operations.
RO = Read Only. Writing has no effect. R/WC = Read / Write to Clear. A CPU write of 1 clears the associated bit to 0.				

MM2S_CURDESC (MM2S DMA Current Descriptor Pointer Register– Offset 08h) (C_INCLUDE_SG = 1)

This register provides a Current Descriptor Pointer for the Memory Map to Stream DMA Scatter Gather Descriptor Management.

Current Descriptor Pointer[31:5]

Rsvd

Figure 2-4: MM2S CURDESC Register

Bits	Field Name	Default Value	Access Type	Description
31 downto 5	Current Descriptor Pointer	zeros	R/W (RO)	In Scatter Gather Mode (C_INCLUDE_SG = 1) indicates the pointer of the current descriptor being worked on. This register must contain a pointer to a valid descriptor prior to writing the TAILDESC register. Otherwise, undefined results occur. When DMACR.RS is 1, CURDESC becomes Read Only (RO) and is used to fetch the first descriptor. When the DMA Engine is running (DMACR.RS=1), CURDESC registers are updated by AXI VDMA to indicate the current descriptor being worked on. On Scatter Gather error detection, CURDESC is updated to reflect the descriptor associated with the detected error. The register can only be written to by the CPU when the DMA Engine is Halted (DMACR.RS=0 and DMASR.Halted =1). At all other times, this register is Read Only (RO). Descriptors must be 8-word aligned, that is, 0x00, 0x20, 0x40, and so on. Any other alignment has undefined results.
				In Register Direct Mode (C_INCLUDE_SG = 0) this field is reserved and always read as zeros.
4 downto 0	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.

Table 2-7: MM2S_CURDESC Register Details

MM2S_TAILDESC (MM2S DMA Tail Descriptor Pointer Register– Offset 10h) (C_INCLUDE_SG = 1)

This register provides the Tail Descriptor Pointer for the Memory Map to Stream DMA Scatter Gather Descriptor Management.

31	5	4	3 2	2 1	0
_		-		_	

Tail Descriptor Pointer[31:5]

Rsvd

Figure 2-5: MM2S_TAILDESC Register

Bits	Field Name	Default Value	Access Type	Description
31 downto 5	Tail Descriptor Pointer	zeros	R/W (RO)	In Scatter Gather Mode (C_INCLUDE_SG = 1), indicates the pause pointer in a descriptor chain. The AXI VDMA SG Engine pauses descriptor fetching after completing operations on the descriptor whose current descriptor pointer matches the tail descriptor pointer. When AXI VDMA Channel is not Halted (DMASR.Halted = 0), a write by the CPU to the TAILDESC register causes the AXI VDMA SG Engine to start fetching descriptors or restart if it was idle (DMASR.Idle = 1). Writing to the TAILDESC when not idle (DMASR.Idle = 0) has undefined results. If the AXI DMA Channel is Halted (DMASR.Halted = 1 and DMACR.RS = 0), a write by the CPU to the TAILDESC register has no effect except to reposition the pause point. Note: Descriptors must be 8-word aligned, that is, 0x00, 0x20, 0x40 and so on. Any other alignment has undefined results. Note: In Register Direct Mode (C_INCLUDE_SG = 0) this field is reserved and always read as zeros.
4 downto 0	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.

Table 2-8: MM2S_TAILDESC Register Details

R/W = Read / Write

MM2S_REG_INDEX (MM2S Register Index - Offset 14h) (C_INCLUDE_SG = 0)

This register provides access to upper bank of 16 (that is, 17 through 32) start addresses.

31	Reserved 1	MM2S_REG_INDEX 0

Figure 2-6: MM2S Register Index

Bits	Field Name	Default/ Reset State	Access	
31 downto 1		Reserved	RO	Always read as zero
			When set, enables access to the next set of 16 Frame Store Start Addresses (Bank1- 17 through 32) depending upon the following cases:	
			Case 1: When C_NUM_FSTORES is less than or equal to 16, Bank1 (17 thru 32) registers are not available. Any writes to this bit do not change the behavior of VDMA.	
			R/W	Case 2: When C_NUM_FSTORES is greater than 16 but less than 32
0	MM2S Reg Index zer	zeroes		 0 = Any write or read access between 0x5C to 0x98 accesses the Bank0 (1 thru 16) Frame StoreStart Address registers. 1 = Accesses Bank1 registers. Example: If C_NUM_FSTORES = 20, Bank0 has 1-16 Frame Store Start Addresses and Bank1 has 17-20 Frame Store Start Addresses above 20 has no effect on writes and returns zero on
				reads. Case 3.: When C_NUM_FSTORES is equal to 32
				• 0 = Any write or read access between 0x5C to 0x98 accesses the Bank0 registers.
				• 1 = Any write or read access between 0x5C to 0x98 accesses the Bank1 registers.

Table 2-9: MM2S Register Index (MM2S_REG_INDEX – Offset 0x14)

Note: MM2S_REG_INDEX register is not present in case of SG=1 mode.

Note: The existing VDMA behavior of Dynamic MM2S Frame Store selection (MM2S) remains unchanged with the addition of the MM2S_REG_INDEX register.

MM2S_FRMSTORE (MM2S Frame Store Register– Offset 18h) (C_INCLUDE_SG = 1/0)

This register provides the number of Frame Stores to use for the Memory Map to Stream channel.

Reserved

Frame Store

Figure 2-7: MM2S_FRMSTORE Register

31

Bits	Field Name	Default Value	Access Type	Description
31 downto 6	Reserved	zeroes	RO	Writing to these bits has no effect, and they are always read as zeros.
5 downto 0	Frame Store	e C_NUM_FSTORES	R/W	Indicates the number of frame stores to use for video data transfers. This value defaults to C_NUM_FSTORES. For Scatter Gather mode (C_INCLUDE_SG = 1), this value specifies the number of Scatter Gather Descriptors required. For Register Direct mode (C_INCLUDE_SG = 0) this value specifies the number of Start Address registers used for transfers. On reset and start-up this register is set to C_NUM_FSTORES.
				Note: Genlock Masters and their attached Genlock Slaves must have identical Frame Store settings. Any mismatch in values has undefined results.
				Note: Values written must be greater than 0 and less than or equal to C_NUM_FSTORES. Any other value has undefined results.
RO = Read Onl		s no effect.	1	
R/W = Read /	Write			

Table 2-10: MM2S_FRMSTORE Register Details

MM2S_THRESHOLD (MM2S Line Buffer Threshold Register– Offset 1Ch) (C_INCLUDE_SG = 1/0)

This register provides the Line Buffer Threshold for the Memory Map to Stream channel.

PARK_PTR_REG (Park Pointer Register – Offset 28h) (C_INCLUDE_SG = 1/0)

This register provides Park Pointer Registers for the Memory Map to Stream and Stream to Memory Map DMA transfer Management.

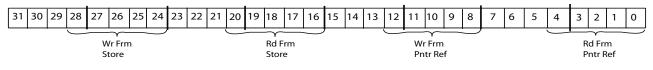

Figure 2-9: PARK_PTR_REG Register

Table 2-12: PARK_PTR_REG Register Details

Bits	Field Name	Default Value	Access Type	Description
31 downto 29	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
28 downto 24	WrFrmStore		RO	Write Frame Store. Indicates current frame being operated on by S2MM channel. During DMA operations this value continually updates as each frame is processed. During error conditions, the value is updated with the current frame being operated on when the error occurred.
23 downto 21	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
20 downto 16	RdFrmStore		RO	Read Frame Store. Indicates current frame being operated on by MM2S channel. During DMA operations this value continually updates as each frame is processed. During error conditions, the value is updated with the current frame being operated on when the error occurred.
15 downto 13	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
12 downto 8	WrFrmPtrRef		R/W	Write Frame Pointer Reference. When Parked (DMACR.Circular_Park = 0), references the S2MM Frame to park on.
7 downto 5	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
4 downto 0	RdFrmPtrRef		R/W	Read Frame Pointer Reference. When Parked (DMACR.Circular_Park = 0) references the MM2S Frame to park on.
RO = Read Onl R/W = Read /	y. Writing has no e Write	ffect.		r

VDMA_VERSION (AXI VDMA Version Register – Offset 2Ch) (C_INCLUDE_SG = 1/0)

This register provides the AXI VDMA Version.

Figure 2-10: VDMA_VERSION Register

Table 2-13: \	/DMA_	VERSION	Register	Details
---------------	-------	---------	----------	---------

Bits	Field Name	Default Value	Access Type	Description	
31 downto 28	Major Version	3h	RO	Single 4-bit hexadecimal value. v1 = 1h, v2=2h, v3=3h, and so on.	
27 downto 20	Minor Version	01h	RO	Two separate 4-bit hexadecimal values. 00 = 00h, 01 = 01h, and so on.	
19 downto 16	Revision	Ah	RO	Revision letter as a hexadecimal character from 'a' to 'f'. Mapping is as follows: Ah-> 'a', Bh -> 'b', Ch-> 'c', and so on.	
15 downto 0	Xilinx Internal	various	RO	Reserved for Internal Use Only. Integer value from 0 to 9999.	
RO = Read Only. Writing has no effect.					

Stream to Memory Map Register Detail

S2MM_DMACR (S2MM DMA Control Register – Offset 30h) (C_INCLUDE_SG = 1/0)

This register provides control for the Stream to Memory Map DMA Channel.

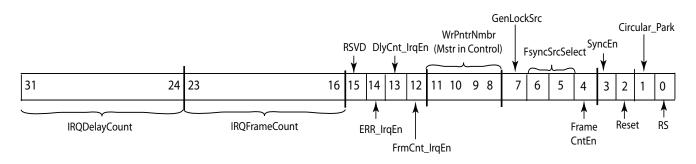

Figure 2-11: S2MM DMACR Register

Bits	Field Name	Default Value	Access Type	Description
31 downto 24	IRQDelayCount	0x00	R/W	This value is used for setting the interrupt delay count value. The delay count interrupt is a mechanism for causing the DMA engine to generate an interrupt after the delay period has expired. This is used for cases when the interrupt frame count is not met after a period of time and the CPU desires an interrupt to be generated. Timer begins counting at the start of a frame and resets with the transfer of a new packet on S2MM stream or when the delay count period has expired. When a value different than the current IRQDelayCount is written to this field, the internal delay counter is reset to zero.
				Note: Setting this value to zero disables the delay counter interrupt.
23 downto 16	IRQFrameCount	01h	R/W	Interrupt Frame Count. This value is used for setting the interrupt threshold. When a frame transfer interrupt events occur, an internal counter counts down from the Interrupt Frame Count setting. On the frame boundary after count reaches 1, an interrupt out is generated by the VDMA engine. When an IRQFrameCount value, different than what is currently set, is written to the IRQFrameCount field, the internal frame counter is reset to the new IRQFrameCount value. Note: The minimum setting for the threshold is 0x01. A write of 0x00 to this register sets the threshold to 0x01.
				Note: When DMACR.FrameCntEn = 1, this value determines the number of frame buffers to process.
15	Reserved	0	RO	Writing to this bit has no effect and it is always read as zeros.
14	Err_IrqEn	0	R/W	 Interrupt on Error Interrupt Enable. When set to 1, allows DMASR.Err_Irq to generate an interrupt out. 0 = Error Interrupt disabled 1 = Error Interrupt enabled
13	DlyCnt_IrqEn	0	R/W	 Delay Count Interrupt Enable. When set to 1, allows DMASR.DlyCnt_Irq to generate an interrupt out. 0 = Delay Count Interrupt disabled 1 = Delay Count Interrupt enabled
12	FrmCnt_IrqEn	0	R/W	 Frame Count Complete Interrupt Enable. When set to 1, allows DMASR.FrmCnt_Irq to generate an interrupt out when IRQFrameCount value reaches zero. 0 = Frame Count Interrupt disabled 1 = Frame Count Interrupt enabled

Bits	Field Name	Default Value	Access Type	Description
11 downto 8	WrPntrNum	zeroes	R/W	Indicates the master in control when S2MM channel is configured for Genlock slave mode (C_S2MM_GENLOCK_MODE = 1). • 0000b = Controlling master is Master 1 • 0001b = Controller master is Master 2 • 0010b = Controller master is Master 3 and so on Note: Maximum valid WrPntrNum is C_S2MM_GENLOCK_NUM_MASTER - 1. Setting to a value greater than C_S2MM_GENLOCK_NUM_MASTER - 1 has undefined results.
7	Genlock Source	0	R/W	 Sets the Genlock source for Genlock slaves 0 = External Genlock 1 = Internal Genlock
6 downto 5	FsyncSrcSelect	00	R/W	 Selects the frame sync source for the S2MM channel. The frame sync source is selected as follows: 00 = s2mm_fsync 01 = mm2s_fsync 10 = s_axis_s2mm_tuser(0) ?] When C_S2MM_ENABLE_SOF = 1 else reserved 11 = Reserved 11 = Reserved Note: Frame Sync Source Select is only valid if configured for external frame sync (C_USE_FSYNC = 1). Note: FsyncSrcSelect option 10b (s_axis_s2mm_tuser(0)) when SOF is enabled, C_S2MM_ENABLE_SOF=1. Else the selection is reserved.
4	FrameCntEn	0	R/W	Configures VDMA to allow only IRQFrameCount number of transfers to occur. After the IRQFrameCount frames are completely transferred, the axi_vdma channel halts, DMACR.RS bit is deasserted and the DMASR.Halted asserts when the channel has completely halted.
3	SyncEn	0	R/W RO	 Enables Genlock synchronization. 0 = Genlock synchronization disabled. Genlock input ignored by S2MM. 1 = Genlock synchronization enabled. MM2S synchronized to Genlock frame input. <i>Note:</i> This value is only valid when the channel is configured as Genlock Slave (C_S2MM_GENLOCK_MODE = 1). If configured fo Genlock Master mode (C_S2MM_GENLOCK_MODE = 0), this bit is reserved and always reads as zero. <i>Note:</i> R/W when C_S2MM_GENLOCK_MODE = 1, Reserved and RO when C_S2MM_GENLOCK_MODE = 0.

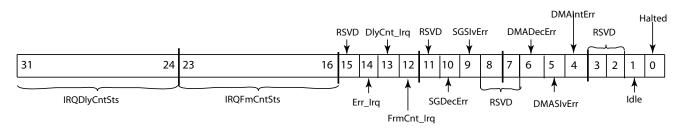

Bits	Field Name	Default Value	Access Type	Description
2	Reset	0	R/W	 Soft reset for resetting the AXI VDMA S2MM channel. Setting this bit to a 1 causes the AXI VDMA S2MM channel to be reserved. Reset is accomplished gracefully. Pending commands/transferred are flushed or completed. AXI4-Stream reset output is asserted. Setting DMACR.Reset = 1 only resets the S2MM channel. After completion of a soft reset, all S2MM registers and bits are in the Reset State. 0 = Reset NOT in progress - Normal operation
				• 1 = Reset in progress
				When set to 1, indicates Circular Buffer Mode and frame buffe are processed in a circular manner. When set to 0, indicates Par Mode and channel will park on the frame buffer referenced by PARK_PTR_REG.RdFrmPntrRef.
			R/W	 0 = Park – Engine will park on the frame buffer referenced b PARK_PTR_REG.RdFrmPntrRef.
1 Ci	Circular_Park	1		 1 = Tail Pointer Mode/Circular Buffer Mode. SG Descriptor processed until the TAILDESC pointer is reached if SG engines is included and start address is cycled through in a circula manner.
				<i>Note:</i> Transitions to/from Park and Circular Buffer modes occur of frame sync boundaries.
				Note: For Scatter Gather Mode (C_INCLUDE_SG = 1), Park Mod must only be enabled when AXI VDMA is Idle (DMASR.Idle = 1) an NOT halted (DMASR.Halted = 0). Undefined results occur if enable at any other time.
			Note: For non-Scatter Gather Mode (C_INCLUDE_SG = 0), Pa Mode can be specified at any time.	
0 RS			Run / Stop. Controls running and stopping of the VDMA channel. For any DMA operations to commence the AXI VDM engine must be running (DMACR.RS=1).	
	RS 0	0	0 R/W	 0 = Stop – VDMA stops when current (if any) DMA operations are complete. The halted bit in the DMA Status Register asserts to 1 when the DMA engine is halted. This bigets cleared by the AXI VDMA hardware when an error occurs. The CPU can also choose to clear this bit to stop DM operations.
				• 1 = Run – Start DMA operations. The halted bit in the DM. Status Register deasserts to 0 when the DMA engine begin operations.
				Note: If Run/Stop is cleared, in-progress stream transfers migh terminate early.

Table 2-14: S2	2MM_DMACR	Register Det	ails <i>(Cont'd)</i>
----------------	-----------	---------------------	----------------------

R/W = Read / Write.

S2MM_DMASR (S2MM DMA Status Register – Offset 34h) (C_INCLUDE_SG = 1/0)

This register provides the status for the Stream to Memory Map DMA Channel.

Bits	Field Name	Default Value	Access Type	Description
31 downto 24	IRQDelayCntSts	00h	RO	Interrupt Delay Count Status. Indicates current interrupt delay time value.
23 downto 16	IRQFrameCntSts	01h	RO	Interrupt Frame Count Status. Indicates current interrupt frame count value.
15	Reserved	0	RO	Always read as zero.
14	Err_Irq	0	R/WC	Interrupt on Error. When set to 1, indicates an interrupt event was generated on error. If enabled (DMACR.Err_IrqEn = 1), an interrupt out is generated from the AXI VDMA. 0 = No error Interrupt. 1 = Error interrupt detected.
13	DlyCnt_Irq	0	R/WC	 Interrupt on Delay. Delay counter begins counting at the beginning of each frame and resets at delay count or transfer of video line. If delay count reached, the bit sets to 1, indicating an interrupt event was generated due to delay counter. If enabled (DMACR.DlyCnt_IrqEn = 1), an interrupt out is generated from the AXI VDMA. 0 = No Delay Interrupt. 1 = Delay Interrupt detected.
12	FrmCnt_Irq	0	R/WC	 Frame Count Interrupt. When set to 1, indicates a Frame Count interrupt event was generated. This occurs when DMACR.FrameCount frames have been transferred. If enabled (DMACR.FrmCnt_IrqEn = 1) and if the interrupt threshold has been met, an interrupt out is generated from the AXI VDMA. 0 = No Frame Count Interrupt. 1 = Frame Count Interrupt detected.
11	Reserved	0	RO	Writing to this bit has no effect, and it is always read as zeros.

Table 2-15: S2MM_DMASR Register Details

Bits	Field Name	Default Value	Access Type	Description
10	SGDecErr	0	RO	 Scatter Gather Decode Error. In Scatter Gather Mode (C_INCLUDE_SG =1) this bit indicates a Decode Error was detected by the Scatter Gather Engine. This error occurs if the address request is to an invalid address (that is, CURDESC and/or NXTDESC points to an invalid address). This error condition causes both AXI VDMA channels (MM2S and S2MM) to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1 for both channels. For Register Direct Mode (C_INCLUDE_SG = 0) this bit is reserved and always read as 0b. 0 = No SG Decode Errors. 1 = SG Decode Error detected. DMA Engine halts. Note: In Scatter / Gather Mode (C_INCLUDE_SG = 1) the CURDESC register is updated with the errored descriptor pointer when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one address is updated to the CURDESC. A reset (soft or hard) must be issued to clear the error condition. Note: On error, in progress stream transfers might terminate early.
9	SGSlvErr	0	RO	 Scatter Gather Slave Error. In Scatter Gather Mode (C_INCLUDE_SG =1) this bit indicates a Slave Error was detected by the Scatter Gather Engine. This error occurs if the slave read from on the Memory Map interface issues a Slave error. This error condition causes both AXI VDMA channels (MM2S and S2MM) to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1 for both channels. For Register Direct Mode (C_INCLUDE_SG = 0) this bit is reserved and always read as 0b. 0 = No SG Slave Errors. 1 = SG Slave Error detected. DMA Engine halts. <i>Note:</i> In Scatter Gather Mode (C_INCLUDE_SG = 1) the CURDESC register is updated with the errored descriptor pointer when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one address is updated to the CURDESC. A reset (soft or hard) must be issued to clear the error condition. <i>Note:</i> On error, in-progress stream transfers might terminate early.
8 downto 7	Reserved	zeros	RO	Writing to these bits has no effect, and they are always read as zeros.

Table 2-15:	S2MM	DMASR	Register	Details	(Cont'd)

Bits	Field Name	Default Value	Access Type	Description
				DMA Decode Error. Decode error detected by primary AXI DataMover. This error occurs if the address request is to an invalid address.
				For Scatter Gather Mode (C_INCLUDE_SG = 1) this situation can happen if the Descriptor Buffer Address points to an invalid address.
				For Register Direct Mode (C_INCLUDE_SG = 0) this situation can happen if the Start Address/es point to an invalid address.
6	DMADecErr	0	RO	This error condition causes the AXI VDMA S2MM channel to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1.
				• 0 = No DMA Decode Errors.
				• 1 = DMA Decode Error detected. DMA channel halts.
				Note: The PRK_PTR_REG.WrFrmStore field is updated with the errored frame reference when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.WrFrmStore. A reset (soft or hard) must be issued to clear the error condition.
				DMA Slave Error.
				Slave error detected by primary AXI DataMover. This error occurs if the slave read from the Memory Map interface issues a Slave Error. This error condition causes the AXI VDMA S2MM channel to halt gracefully. The DMACR.RS bit is set to 0, and when the engine has completely shut down, the DMASR.Halted bit is set to 1.
5	DMASlvErr	0	RO	• 0 = No DMA Slave Errors.
		0		• 1 = DMA Slave Error detected. DMA Engine halts.
				Note: The PRK_PTR_REG.WrFrmStore field is updated with the errored frame reference when this error is detected. If multiple errors are detected, the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.WrFrmStore. A reset (soft or hard) must be issued to clear the error condition.
				<i>Note:</i> On error, in-progress stream transfers might terminate early.

Table 2-15: S2MM_DMASR Register Details (Cont'd)

Bits	Field Name	Default Value	Access Type	Description
4	DMAIntErr	0	RO	 DMA Internal Error. Internal error detected by primary AXI DataMover. This error can occur if a 0 length bytes to transfer is fed to the AXI DataMover. For Scatter Gather Mode this situation can happen if the vertical size (vsize) and/or the horizontal size (hsize) specified in the fetched descriptor is set to 0. For Register Direct Mode (C_INCLUDE_SG = 0) this situation can happen if the vertical size (vsize) and/or the horizontal size (hsize) specified in S2MM_VSIZE and S2MM_HSIZE respectively is set to 0. If in free run mode (C_USE_FSYNC = 0), the channel is shut down. DMACR.RS bit is set to 0 and when the engine has completely shut down, the DMASR.Halted bit is set to 1. A reset (Soft or Hard) needs to be issued to clear the error condition. If not in external frame sync mode or not in flush on frame sync mode, the PARK_PTR_REF.WrFmStore field is updated with the errored frame reference when this error is detected.This error condition causes the AXI VDMA S2MM channel to halt gracefully. 0 = No DMA Internal Errors. 1 = DMA Internal Error detected. DMA channel halts. Internal Error can also occur if a packet greater or less than hsize bytes is transmitted. For this type of error, if external frame sync is enabled (C_USE_FSYNC=1) and Flush On Frame Sync is enabled (C_FLUSH_ON_FSYNC = 1), then on the next frame sync the channel is flushed, reset, and DMA processing begins again. <i>Note:</i> The PRK_PTR_REG.WrFrmStore field is updated with the errors are logged in the DMASR, but only one reference is updated to PRK_PTR_REG.WrFrmStore. A reset (soft or hard) must be issued to clear the error condition.
3 downto 2	Reserved	0	RO	Writing to these bits has no effect and they are always read as zeros.

Bits	Field Name	Default Value	Access Type	Description
				DMA Scatter Gather Engine Idle. In Scatter Gather Mode (C_INCLUDE_SG = 1) this bit indicates the state of AXI VDMA Scatter Gather Engine operations. The assertion of Idle indicates the SG Engine has reached the tail pointer for the associated channel and all queued descriptors have been processed. If in the Idle state (DMASR.Idle = 1), writing to the TailPointer register automatically restarts DMA operations. For Register Direct Mode (C_INCLUDE_SG = 0) this bit is
1	Idle	0	RO	reserved and always read as 0b.
				 0 = Not Idle - SG operations for S2MM channel in progress. 1 = Idle - SG operation for S2MM channel paused.
				Note: DMASR.Idle only asserts after the SG engine has passed through the descriptor chain at least once and has reached the TAILDESC.
				Note: Writing to the TAILDESC register when not Idle (DMASR.Idle = 0) produces undefined results.
				DMA Channel Halted.
				Indicates the run/stop state of the DMA channel.
0	Halted	1	RO	 0 = DMA channel running 1 = DMA channel halted. This bit gets set when DMACR.RS = 0 and DMA and SG operations have halted. There can be a lag of time between when DMACR.RS = 0 and when DMASR.Halted = 1.
				Note: When halted (RS= 0 and Halted = 1), writing to CURDESC or TAILDESC pointer registers has no effect on DMA operations.
RO = Read Only	. Writing has no ef	fect	1	

Table 2-15:	S2MM	DMASR	Register	Details	(Cont'd))
-------------	------	-------	----------	---------	----------	---

R/WC = Read / Write to Clear. A CPU write of 1 clears the associated bit to 0.

S2MM_CURDESC (S2MM DMA Current Descriptor Pointer Register- Offset 38h) (C_INCLUDE_SG = 1)

This register provides the Current Descriptor Pointer for the Stream to Memory Map DMA Scatter Gather Descriptor Management.

Current Descriptor Pointer[31:5]

Rsvd

Figure 2-13: S2MM CURDESC Register

Bits	Field Name	Default Value	Access Type	Description
31 downto 6	Current Descriptor Pointer	zeros	R/W (RO)	In Scatter Gather Mode (C_INCLUDE_SG = 1) indicates the pointer of the current descriptor being worked on. This register must contain a pointer to a valid descriptor prior to writing to the TAILDESC register; otherwise, undefined results occur. When DMACR.RS is 1, CURDESC becomes Read Only (RO) and is used to fetch the first descriptor. When the DMA Engine is running (DMACR.RS=1), CURDESC registers are updated by AXI VDMA to indicate the current descriptor being worked on. On Scatter Gather error detection, CURDESC is updated to reflect the descriptor associated with the detected error. The register can only be written to by the CPU when the DMA Engine is Halted (DMACR.RS=0 and DMASR.Halted =1). At all
				other times, this register is Read Only (RO). Descriptors must be 8 word aligned, that is, 0x00, 0x20, 0x40, and so on. Any other alignment has undefined results.
				Note: In Register Direct Mode (C_INCLUDE_SG = 0) this field is reserved and always read as zeros.
5 downto 0 (Offset 0x38)	Reserved	0	RO	Writing to these bits has no effect, and they are always read as zeros.
RO = Read On R/W = Read /	ly. Writing has n Write.	o effect.	1	

Table 2-16: S2MM_CURDESC Register Details

S2MM_TAILDESC (S2MM DMA Tail Descriptor Pointer Register– Offset 40h) (C_INCLUDE_SG = 1)

This register provides the Tail Descriptor Pointer for the Stream to Memory Map DMA Scatter Gather Descriptor Management.

Chapter 3

Customizing and Generating the Core

Generating the Core Using CORE Generator

The AXI VDMA can be found in **AXI Infrastructure/Video & Image Processing** in the CORE GeneratorTM tool graphical user interface (GUI) **View by Function** pane.

To access the AXI VDMA, do the following:

- Open a project by selecting File > Open Project or create a new project by selecting File > New Project.
- 2. With an open project, choose **AXI Infrastructure/Video & Image Processing** in the **View by Function** pane.
- 3. Double-click AXI Video Direct Memory Access to display the AXI VDMA GUI.

CORE Generator Tool Parameter Screen

The AXI VDMA GUI contains one screen (Figure 3-1) that provides information about the core, allows for configuration of the core, and provides the ability to generate the core.

View Documents IP Symbol #X IV Ideo Direct Memory Access #W #X IV Ideo Direct Memory Access xilinx.com/ip/axil_vdma.5.00.a MAX Max </th

Figure 3-1: AXI VDMA GUI

Component Name

The base name of the output files generated for the core. Names must begin with a letter and can be composed of any of the following characters: a to z, 0 to 9, and "_".

DMA Options

The following subsections describe options that affect both channels of the AXI VDMA core.

Frame Stores

Frame Stores indicates the number of frame buffer storage locations to be processed by the AXI VDMA. In Register Direct Mode (C_INCLUDE_SG = 0) this value determines the number of valid Start Addresses per channel that need to be initialized. For Scatter Gather mode (C_INCLUDE_SG = 1) this parameter defines the number of Scatter Gather descriptors per channel in the descriptor chain required to initialize the AXI VDMA. Valid values are 1 to 32.

Use Frame Sync

This option is used to set the synchronization mode of the AXI VDMA. Uncheck to select Free Run Mode and check to select Frame Sync Mode. In Free Run Mode the AXI VDMA transfers data as quickly as it is able to. When in Frame Sync Mode, the AXI VDMA transfers data starting with the falling edge of each mm2s_fsync or s2mm_fsync for the associated channel.

Enable Scatter Gather Engine

Checking this option enables Scatter Gather Mode operation and includes the Scatter Gather Engine in AXI VDMA. Unchecking this option enables Register Direct Mode operation, excluding the Scatter Gather Engine from AXI VDMA. Disabling the Scatter Gather Engine causes all output ports for the Scatter Gather engine to be tied to zero, and all of the input ports to be left open.

Enable Video Parameter Reads

Checking this option enables the reading of the video transfer parameters (vsize, hsize, stride, and frame delay) and start addresses using the s_axi_lite control interface. For applications where reading of the video transfer parameters is not needed then unchecking this option disables reading of video transfer parameters which saves FPGA resources.

Interrupt Delay Timer Resolution

This integer value sets the resolution of the Interrupt Delay Counter. Values specify the number of clock cycles between each tick of the delay counter. If Scatter Gather Engine is enabled, clock cycles are based on the m_axi_sg_aclk clock input. If Scatter Gather Engine is disabled, clock cycles are based on s_axi_lite_aclk clock cycles.

Enable Asynchronous Clocks

This setting allows operation of the MM2S interface m_axi_mm2s_aclk, S2MM interface m_axi_s2mm_aclk, AXI4-Lite control interface s_axi_lite_aclk, and the Scatter Gather Interface m_axi_sg_aclk to be asynchronous from each other. When Asynchronous Clocks are enabled, the frequency of s_axi_lite_aclk must be less than or equal to m_axi_sg_aclk. When Asynchronous Clocks are disabled, all clocks must be at the same frequency and from the same source.

Enable Flush on Frame Sync

This setting enables the AXI VDMA to reset internal states and flush transfer data on frame sync. This allows VDMA to restart transfers at the beginning of a new frame after DMA Internal error detection as opposed to halting. This feature is only enabled when C_USE_FSYNC=1.

Include Internal Genlock Bus

This setting allows internal routing of MM2S and S2MM Genlock buses without having connecting them outside the core.

MM2S Channel Options

The following subsections describe options that affect only the MM2S Channel of the AXI VDMA core.

Enable Channel

This option enables or disables the MM2S channel. Enabling the MM2S channel allows read transfers from memory to AXI4-Stream to occur. Disabling the MM2S channel excludes the logic from the AXI VDMA core. Outputs for the MM2S channel are tied to zero and inputs are ignored by AXI VDMA.

Memory Map Data Width

Data width in bits of the AXI MM2S Memory Map Read data bus. Valid values are 32, 64, 128, 512 and 1024.

Stream Data Width

Data width in bits of the AXI MM2S AXI4-Stream data bus. Valid values are 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, and 1024. This value must be less than or equal to Memory Map Data Width.

Allow Unaligned Transfers

Enables or disables the MM2S Data Realignment Engine. When checked, the data realignment engine is enabled and allows data realignment to the byte (8 bits) level on the MM2S Memory Map datapath. The MM2S channel reads the vertical size (vsize) number of video lines each horizontal size (hsize) bytes long and spaced stride bytes apart (stride is number of bytes between first pixel of each line) from memory. For the case where unaligned transfers are allowed, data reads can start from any Start Address byte offset, be of any horizontal size and stride value. The read data are aligned such that the first byte read is the first valid byte out on the AXI4-Stream.

When unchecked, that is, for the case where unaligned transfers are *not* allowed, the Start Address must be aligned to multiples of C_M_AXI_MM2S_DATA_WIDTH bytes. Also Horizontal Size and Stride must be specified in even multiples of C_M_AXI_MM2S_DATA_WIDTH bytes.

For example, if C_M_AXI_MM2S_DATA_WIDTH = 32, data is aligned if the Start Address at word offsets (32-bit offset), that is, 0x0, 0x4, 0x8, 0xC, and so on., Horizontal Size is 0x4, 0x8, 0xC and so on. Stride is 0x4, 0x8, 0xC, and so on.

If C_M_AXI_MM2S_DATA_WIDTH = 64, data is aligned if the Start Address is at double-word offsets (64-bit offsets), that is, 0x0, 0x8, 0x10, 0x18, and so on, and Horizontal Size, and Stride are at 0x4, 0x8, 0xC, and so on.

Note: If Allow Unaligned Transfers is unchecked then unaligned start addresses, hsizes, or strides, are not supported. Having an unaligned Start Address, HSize, and/or Stride results in undefined behavior.

Note: Further the Data Realignment Engine only supports AXI4-Stream data width setting of 64-bits and less.

Enable Store and Forward

This option enables or disables the Store and Forward buffer for the MM2S channel. When enabled, read requests on MM2S are only made if there is enough buffer space in the Store-and-Forward buffer to complete the burst. When MM2S Line Buffer Depth is not zero and Store and Forward is enabled, the stream valid signal, m_axis_mm2s_tvalid, does not assert until a minimum Line Buffer Threshold bytes have been read and stored in the Store-And-Forward buffer.

Maximum Burst Size

This option specifies the maximum size of the burst cycles on the AXI MM2S Memory Map Read interface. In other words, this setting specifies the granularity of burst partitioning. For example, if the burst length is set to 16, the maximum burst on the memory map interface is 16 data beats. Smaller values reduce throughput but result in less impact on the AXI infrastructure. Larger values increase throughput but result in a greater impact on the AXI infrastructure. Valid values are 16, 32, 64, 128, and 256.

Genlock Mode

This option sets the Genlock Mode of the MM2S Channel. Selecting **Master** enables master mode and specifies that the MM2S channel operate as a Genlock Master. In Master mode, frames are not dropped or repeated. The current master frame being worked on by the MM2S channel is specified on the mm2s_frm_ptr_out port. Selecting **Slave** enables slave mode and specifies that the MM2S channel operate as a Genlock Slave. In Slave mode, frames are automatically dropped or repeated based on the master and slave frame rates. The Genlock slave looks at the vector slice of mm2s_frm_ptr_in as specified in the MM2S DMACR Read Pointer Number field (DMACR.RdPntrNmbr bits 11 downto 8) to determine which frame the master is working on and operates a minimum Frame Delay behind the master.

Number of Masters

This setting specifies to the Genlock slave the total number of masters to synchronize operations to. This setting also specifies the vector width of the mm2s_frm_ptr_in port, where each master requires 6 bits on the mm2_frm_ptr_in vector. Therefore, the width of the mm2s_frm_ptr_in port is 6*Number of Masters. Valid values are 1 to 16.

Line Buffer Depth

This setting specifies the inclusion of an MM2S Line Buffer and also specifies the depth. A setting of zero excludes the line buffer from the MM2S Channel. A non-zero value includes the Line Buffer and sets the depth in bytes of the line buffer. The line buffer resides on the MM2S AXI4-Stream Interface. Valid minimum depth, excluding 0, equals C_M_AXIS_MM2S_TDATA_WIDTH/8, must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is nearest to the upper power of 2 value. See C_MM2S_LINEBUFFER_DEPTH in Parameter Descriptions for more details.

Line Buffer Threshold

This specifies the almost full threshold value of the MM2S_THRESHOLD register at which the almost full flag asserts/deasserts. This value is ignored by AXI VDMA if the Line Buffer Depth is set to 0. This value must be a resolution of AXI4-Stream data width in bytes (C_M_AXIS_MM2S_TDATA_WIDTH/8), with a minimum setting of C_M_AXIS_MM2S_TDATA_WIDTH/8 and a maximum setting of Line Buffer Depth (C_MM2S_LINEBUFFER_DEPTH).

Note: If C_M_AXIS_MM2S_TDATA_WIDTH is a non-power of 2, then the line buffer threshold value should be calculated based on the nearest upper power of 2 value. For example, if C_M_AXIS_MM2S_TDATA_WIDTH = 24, then the threshold values should be calculated based on the nearest upper power of 2. That is, C_M_AXIS_MM2S_TDATA_WIDTH = 32. See C_MM2S_LINEBUFFER_THRESH in Parameter Descriptions for more details.

Enable Frame Advancement on Error

This setting enables or disables the MM2S Channel frame advancement on error when the channel is selected and operating as a master and Flush on Frame Sync setting is enabled. When an error is detected in a particular frame, this setting allows the user to let the frame number advance on the next frame sync or not advance and re-use the errored frame's frame number. This is used in applications where it is desired to hide the errored frame.

Enable Start Of Frame on tuser(0)

This setting enables SOF generation for MM2S channel. SOF pulse is driven on m_axis_mm2s_tuser(0) coincident with first pixel of first line for each frame.

S2MM Channel Options

The following subsections describe options that affect only the S2MM Channel of the AXI VDMA core.

Enable Channel

This setting enables or disables the S2MM Channel. Enabling the S2MM Channel allows write transfers from AXI4-Stream to memory to occur. Disabling the S2MM Channel excludes the logic from AXI VDMA core. Outputs for S2MM channel are tied to zero and inputs are ignored by AXI VDMA.

Clock Frequency

This setting specifies the clock frequency in hertz of the S2MM interface clock, m_axi_s2mm_aclk. This parameter is used when Asynchronous Clocks are enabled and configures the AXI VDMA for proper clock domain crossings. When Asynchronous Clocks are disabled, this setting is ignored by AXI VDMA.

Memory Map Data Width

Data width in bits of the AXI S2MM Memory Map Write data bus. Valid values are 32, 64, 128, 512 and 1024.

Stream Data Width

Data width in bits of the AXI S2MM AXI4-Stream Data bus. Valid values are 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, and 1024. This value must be less than or equal to Memory Map Data Width.

Allow Unaligned Transfers

Enables or disables the S2MM Data Realignment Engine. When checked, the data realignment engine is enabled and allows data realignment to the byte (8 bits) level on the S2MM Memory Map datapath. For the case where Unaligned transfers are allowed, data writes can target any Start Address byte offset, be of any horizontal size and stride value; the write data is aligned such that the first byte received on AXI4-Stream is the first valid byte written to the specified memory offset.

When unchecked, that is, for the case where unaligned transfers are *not* allowed, the Start Address must be aligned to multiples of C_M_AXI_S2MM_DATA_WIDTH bytes. Also Horizontal Size and Stride must be specified in even multiples of C_M_AXI_S2MM_DATA_WIDTH bytes.

For example, if C_M_AXI_S2MM_DATA_WIDTH = 32, data are aligned if the Start Address at word offsets (32-bit offset), that is, 0x0, 0x4, 0x8, 0xC, and so on, Horizontal Size is 0x4, 0x8, 0xC and so on, Stride is 0x4, 0x8, 0xC, and so on.

If C_M_AXI_S2MM_DATA_WIDTH = 64, data are aligned if the Start Address is at double-word offsets (64-bit offsets), that is, 0x0, 0x8, 0x10, 0x18, and so on, and Horizontal Size, and Stride are at 0x4, 0x8, 0xC, and so on.

Note: If Allow Unaligned Transfers is unchecked, then unaligned start addresses, hsizes, or strides, are not supported. Having an unaligned Start Address, HSize, and/or Stride results in undefined behavior.

Note: Further, the Data Realignment Engine only supports AXI4-Stream data width setting of 64-bits and less.

Enable Store and Forward

This option enables or disables the Store and Forward buffer for the S2MM channel. When enabled, writes are only requested if all of the write data to complete the burst is stored in the Store-and-Forward buffer.

Note: On S2MM if data bus upsizing is required, that is, Stream Data Width does not equal Memory Map Data Width, then throttles $(m_axi_s2mm_wvalid = 0)$ between data beat writes are observed during the packing processes. For example, if Stream Data Width = 16 and Memory Map Data Width = 32 then throttles occur every 2 clocks. The maximum throttle case would be when the Stream Data Width = 8 and Memory Map Data Width = 256 giving a 32 clock throttle between data beats.

Maximum Burst Size

This setting specifies the maximum size of the burst cycles on the AXI S2MM Memory Map Write interface. In other words, this setting specifies the granularity of burst partitioning. For example, if the burst length is set to 16, the maximum burst on the memory map interface is 16 data beats. Smaller values reduce throughput but result in less impact on the AXI infrastructure. Larger values increase throughput but result in a greater impact on the AXI infrastructure. Valid values are 16, 32, 64, 128, and 256.

Genlock Mode

This option sets the Genlock Mode of the S2MM Channel. Selecting **Master** enables master mode and specifies that the S2MM channel operate as a Genlock Master. In Master mode, frames are not dropped or repeated. The current master frame being worked on by the S2MM channel is specified on the s2mm_frm_ptr_out port. Selecting **Slave** enables slave mode and specifies that the S2MM channel operate as a Genlock Slave. In Slave mode, frames are automatically dropped or repeated based on the master and slave frame rates. The Genlock slave looks at the vector slice of s2mm_frm_ptr_in as specified in the S2MM DMACR Write Pointer Number field (DMACR.WrPntrNmbr bits 11 downto 8) to determine which frame the master is working on and operates a minimum Frame Delay behind the master.

Number of Masters

This setting specifies to the Genlock slave the total number of masters to synchronize operations to. This setting also specifies the vector width of the s2mm_frm_ptr_in port, where each master requires 5 bits on the mm2_frm_ptr_in vector. Therefore the width of the s2mm_frm_ptr_in port is 5*Number of Masters. Valid values are 1 to 16.

Line Buffer Depth

This specifies the inclusion of an S2MM Line Buffer and also specifies the depth. A setting of zero excludes the line buffer from the S2MM Channel. A non-zero value includes the Line Buffer and sets the depth in bytes of the line buffer. The line buffer resides on the S2MM AXI4-Stream Interface. Valid minimum depth, excluding 0, equals C_S_AXIS_S2MM_TDATA_WIDTH/8, must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is the nearest upper power of 2 value. See C_S2MM_LINEBUFFER_DEPTH in Parameter Descriptions for more details.

Line Buffer Threshold

This specifies the almost full threshold value of the S2MM_THRESHOLD register at which the almost full flag asserts/deasserts. This value is ignored by AXI VDMA if the Line Buffer Depth is set to 0. This value must be a resolution of the AXI4-Stream data width in bytes (C_S_AXIS_S2MM_TDATA_WIDTH/8), with a minimum setting of C_S_AXIS_S2MM_TDATA_WIDTH/8 and a maximum setting of Line Buffer Depth (C_S2MM_LINEBUFFER_DEPTH).

Note: If C_S_AXIS_S2MM_TDATA_WIDTH is a non-power of 2, the line buffer threshold value should be calculated based on the nearest upper power of 2 value. For example if C_S_AXIS_S2MM_TDATA_WIDTH = 24, the threshold values should be calculated based on the nearest upper power of 2. That is, C_S_AXIS_S2MM_TDATA_WIDTH = 32. See C_S2MM_LINEBUFFER_THRESH in Parameter Descriptions for more details.

Enable Start Of Frame on tuser(0)

This setting along with FsyncSrcSelect = 10 enables SOF detection for S2MM channel on $s_axis_s2mm_tuser(0)$. SOF pulse received on $s_axis_s2mm_tuser(0)$ coincident with the first pixel of the first line for each frame.

Enable Frame Advancement on Error

This setting enables or disables the S2MM Channel frame advancement on error when the channel is selected and operating as a master and Flush on Frame Sync setting is enabled. When an error is detected in a particular frame, this setting allows the user to let the frame number advance on the next frame sync or not advance and re-use the errored frame's frame number. This setting is used in applications where it is desired to hide the errored frame.

Generating the Core Using EDK

The AXI VDMA can be found in **IP Catalog - EDK_Install/DMA and Timer** in the Xilinx Platform Studio tool graphical user interface (GUI).

To access the AXI VDMA, do the following:

- Invoke Xilinx Platform Studio and open a project by selecting File > Open Project or create a new project by selecting File > New Project.
- 2. With an open project, choose EDK_Install/DMA and Timer.
- 3. Double-click AXI Video DMA to display the AXI VDMA GUI.

For a new project:

- 1. Invoke Xilinx Platform Studio and create New Project using Base System Builder.
- 2. Select Interconnect Type (AXI System) and then select Board Name (based on 6/7 series FPGA)
- 3. After BSB is created, add AXI VDMA from IP catalog (EDK_Install/DMA and Timer) by double clicking AXI Video DMA 5.00.a. This opens up an EDK GUI which is described in the next section.

EDK pCore GUI

The AXI VDMA EDK GUI provides information about the core, allows for configuration of the core, and provides the ability to generate the core. The pCore is generated with each option set to the default value. Figure 3-2 illustrates the EDK pCore GUI for the AXI VDMA. All of the options in the EDK pCore GUI correspond to the same options in the CORE Generator tool GUI.

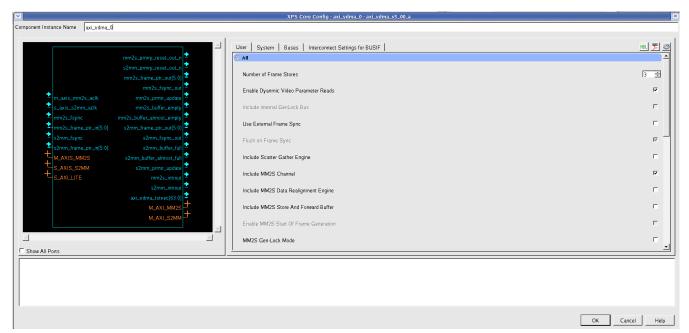

Figure 3-2: EDK pCore GUI

Output Generation

The output files generated from the CORE Generator tool are placed in the project directory. The file output list can include some or all of the following files.

Directory Hierarchy

<project directory>

Top-level project directory for the CORE Generator tool

contains the AXI VDMA doc and source files.

- caxi_vdma_component name>/doc Contains the AXI VDMA solution PDF documentation.
- caxi_vdma_component name>/hdl/src/vhdl Contains the source files for AXI VDMA core.

File Details

<project directory>

This is the top-level file. It contains templates for instantiation the core and the xco file.

Table 3-1: Project Directory

Name	Description
<project_d< th=""><th>lir></th></project_d<>	lir>
<axi_vdma_component_name>.xco</axi_vdma_component_name>	Log file from CORE Generator tool describing which options were used to generate the AXI VDMA core. An XCO file is generated by the CORE Generator tool for each core that it creates in the current project directory. An XCO file can also be used as an input to the CORE Generator tool.
<axi_vdma_component_name>_flist.txt</axi_vdma_component_name>	A text file listing all of the output files produced when the customized AXI VDMA core was generated in the CORE Generator tool.
<axi_vdma_component_name>.vho</axi_vdma_component_name>	The HDL template for instantiating the AXI VDMA core.
<axi_vdma_component_name_synth>.vhd</axi_vdma_component_name_synth>	The HDL synthesis wrapper file with the modified parameter configuration of AXI VDMA core.
<axi_vdma_component_name_sim>.vhd</axi_vdma_component_name_sim>	The structural simulation model for the AXI VDMA core. It is used for functionally simulating the core.

Back to Top

<project directory>/<axi_vdma_component name>

This directory contains the doc and hdl folder.

<axi_vdma_component name>/doc

This directory contains the appropriate product guide.

<project_dir>/<axi_vdma_co< td=""><td>mponent_name>/doc</td></axi_vdma_co<></project_dir>	mponent_name>/doc
axi_vdma_v5_00_a_readme.txt axi_vdma_v5_00_a_readme_vinfo.html	The AXI VDMA release notes and core information file in text and html format.
pg020_axi_vdma.pdf	The AXI VDMA Product Guide.

Back to Top

<axi_vdma_component name>/hdl/src/vhdl

This directory contains AXI VDMA source files including the proc_common, AXI SG, AXI Data Mover helper library files.

Chapter 4

Designing with the Core

Clocking

AXI VDMA provides two clocking modes of operation: asynchronous and synchronous. Asynchronous mode DMA control, Scatter Gather Engine, MM2S and S2MM Primary datapaths can all run asynchronously from each other. Setting C_PRMRY_IS_ACLK_ASYNC = 1 enables this mode and creates six clock domains.

- AXI4-Lite clock domain clocked by s_axi_lite_aclk
- Scatter Gather clock domain clocked by m_axi_sg_aclk
- mm2s clock domain on Memory Map side clocked by m_axi_mm2s_aclk
- s2mm clock domain on Memory Map side clocked by m_axi_s2mm_aclk
- s2mm clock domain on streaming side clocked by s_axis_s2mm_aclk
- mm2s clock domain on streaming side clocked by m_axis_mm2s_aclk

See Figure 4-1. This setting allows high-performance users to run the primary datapaths at higher clock rates than the DMA control (AXI4-Lite interface, SG Engine, DMA Controller, and so on) helping in FPGA placement and timing.

www.xilinx.com

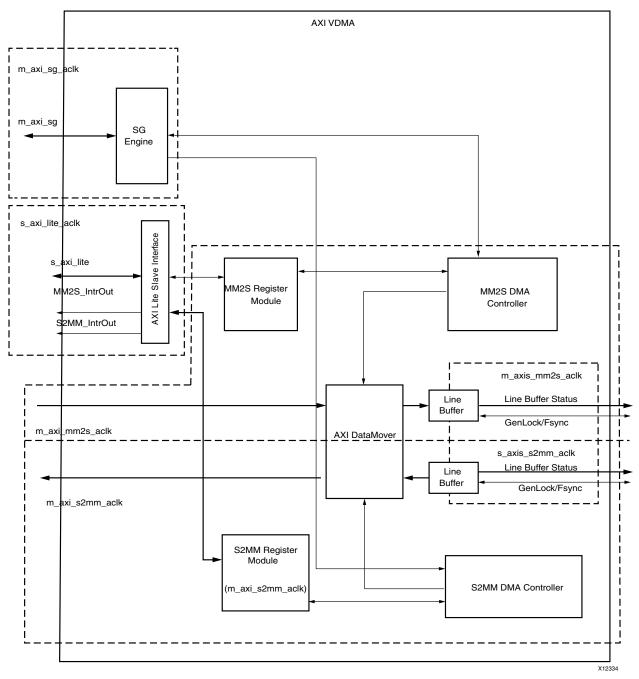

Figure 4-1: Asynchronous Mode Clock Domains

In synchronous mode, C_PRMRY_IS_ACLK_ASYNC = 0, all logic runs in a single clock domain. The signals s_axi_lite_aclk, m_axi_sg_aclk, m_axi_mm2s_aclk, m_axi_s2mm_aclk, m_axis_mm2s_aclk, and s_axis_s2mm_aclk must be tied to the same source otherwise undefined results occur.

www.xilinx.com

Dynamic Clock Feature

The ability to change the primary datapath clocks dynamically provides for a method to support different video resolutions without rebuilding the system. With this feature the fixed relative clock frequency restriction has been removed by redesigning all clock domain crossings within AXI VDMA to not depend on the relative clock rates.

To support this feature, asynchronous First In First Outs (FIFOs) are instantiated for the line buffers with a minimum depth of 512 regardless of the setting of C_MM2S_LINEBUFFER_DEPTH and C_S2MM_LINEBUFFER_DEPTH. This allows the new axis clocks to be varied dynamically.

Limitation:

Changing the clock frequency during operation has a system-wide effect. Therefore, system considerations must be addressed to support dynamic clock changing. To fully support dynamic changing of all clocks, the AXI4 Memory Map targets must be able to support dynamic clock changes and the AXI4-Stream targets must be able to support dynamic clock changes. Support for dynamic clock changing on a system level is outside of AXI VDMA control and is beyond the scope of this document. As such dynamic clock changing the clock frequency during run time) of s_axi_lite_aclk, m_axi_sg_aclk, m_axi_mm2s_aclk, and m_axi_s2mm_aclk is *not* supported. If during operation a clock change is required on s_axi_lite_aclk, m_axi_sg_aclk, or m_axi_s2mm_aclk then a system reset is required.

Supported:

Dynamic Clock changing is supported on the AXI4-Stream. Two new clocks have been added for clocking the AXI4-Stream interfaces, m_axis_mm2s_aclk and s_axis_s2mm_aclk. These two new clocks allow separation of Video IP clocks from the AXI4 clock domain. This allows users to dynamically change the stream clock without affecting the AXI Interconnect, AXI Memory controller, and so on. These two new clock ports have the added benefit of not locking the AXI4 subsystem for very slow video clock rates.

Table 4-1 illustrates which signals and signal sets are clocked by what clock in asynchronous mode.

Target FPGA	C_INCLUDE_SG = 1	C_INCLUDE_SG = 0
s_axi_lite_aclk	All s_axi_lite_* Signals	All s_axi_lite_* Signals
	mm2s_introut	mm2s_introut
	s2mm_introut	s2mm_introut
	axi_resetn	axi_resetn
m_axi_sg_aclk	All m_axi_sg_* Signals	NA
m_axi_mm2s_aclk	All m_axi_mm2s_* Signals	All m_axi_mm2s_* Signals
	mm2s_prmry_reset_out_n	mm2s_prmry_reset_out_n
m_axi_s2mm_aclk	All m_axi_s2mm_* Signals	All m_axi_s2mm_* Signals
	s2mm_prmry_reset_out_n	s2mm_prmry_reset_out_n
m_axis_mm2s_aclk	All m_axis_mm2s_* Signals	All m_axis_mm2s_* Signals
	mm2s_axis_resetn	mm2s_axis_resetn
	mm2s_fsync	mm2s_fsync
	mm2s_fsync_out	mm2s_fsync_out
	mm2s_prmtr_update	mm2s_prmtr_update
	mm2s_frame_ptr_in	mm2s_frame_ptr_in
	mm2s_frame_ptr_out	mm2s_frame_ptr_out
	mm2s_buffer_empty	mm2s_buffer_empty
	mm2s_buffer_almost_ empty	mm2s_buffer_almost_empty
s_axis_s2mm_aclk	All s_axis_s2mm_* Signals	All s_axis_s2mm_* Signals
	s2mm_axis_resetn	s2mm_axis_resetn
	s2mm_fsync	s2mm_fsync

	s2mm_buffer_almost_full	s2mm_buffer_almost_full

Table 4-1: Asynchronous Mode Clock Distribution (C_PRMRY_IS_ACLK_ASYNC = 1)

Resets

The AXI VDMA uses a single Active-Low reset input signal axi_resetn. When this signal is asserted Low, it resets the entire AXI VDMA core. The reset signal must be synchronous to the s_axi_lite_aclk signal and should be asserted for a minimum of eight clock cycles of the slowest clock. This is considered a hard reset and there is no graceful completion of transactions; all registers are reset to power-on conditions; all queues are flushed; all internal logic is returned to power-on conditions.

The reset input axi_aresetn is registered on input to break long timing paths and help with timing closure. Also in reset distribution, the resets out of the reset module are registered for improved timing closure. These pipeline delays along with clock domain crossing logic when in asynchronous mode cause increased reset response time in AXI VDMA and specifies minimum/maximum reset pulse times.

AXI VDMA also provides Soft Reset via the DMA Control Register for each channel. Issuing a Soft Reset by setting MM2S DMA Control Register's Reset bit to 1 or S2MM DMA Control Register's Reset bit to 1 causes the respective channel to reset gracefully. Ongoing transfers will complete including any queued transfers. Resetting one channel via the DMA Control Register does *not* Reset the other channel.

AXI VDMA also provides separate reset output signals MM2S Reset Out and S2MM Reset Out on both channels.

Design Parameters

The AXI VDMA design parameters are listed and described in Table 4-2. In addition to the parameters listed in this table, there are also parameters that are inferred for each AXI interface in the EDK tools. Through the design, these EDK-inferred parameters control the behavior of the AXI Interconnect. For a complete list of the interconnect settings related to the AXI interface, see the *AXI Interconnect IP Data Sheet* (DS768).

Table 4-2:	AXI VDMA Design Paran	neters Description
------------	-----------------------	--------------------

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
	AXI V	DMA Gener	al Parameters	
C_S_AXI_LITE_DATA_WIDTH	32	32	integer	Data width in bits of AXI4-Lite interface
C_S_AXI_LITE_ADDR_WIDTH	32	32	integer	Address width in bits of AXI4-Lite interface
C_DLYTMR_RESOLUTION	1 - 1000000	125	integer	Resolution of the interrupt delay timer in m_axi_sg_aclk cycles when C_INCLUDE_SG = 1 or s_axi_lite_aclk cycles when C_INCLUDE_SG = 0

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_PRMRY_IS_ACLK_ASYNC	0, 1	0	integer	 Specifies whether AXI VDMA is operating in an asynchronous mode or a synchronous mode. Setting to 1 enables asynchronous operation. In this mode all clocks can be asynchronous to each other. If building with XPS, this parameter is automatically set. 0 = All Clocks Synchronous 1 = All Clocks Asynchronous <i>Note:</i> This parameter must be set to 1 if at least one AXI VDMA clock is asynchronous from the other clocks.
C_NUM_FSTORES	1 - 32	3	integer	Value used to specify the maximum number of frame buffers to create and use in external memory. This value also specifies the number of Scatter Gather Descriptors to use in a descriptor chain and the number of video Start Address registers.
C_USE_FSYNC	0, 1	0	integer	 Specifies DMA operations synchronized to frame sync input. 0 = Free Running 1 = Synchronous
C_ENABLE_VIDPRMTR_READS	0, 1	1	integer	 Specifies if video parameters are readable by s_axi_lite interface when configured for Register Direct Mode. Disabling video parameter register reads reduces FPGA resource utilization. 0 = Disable Video Parameter Reads 1 = Enable Video Parameter Reads
C_FLUSH_ON_FSYNC	0, 1	1	Integer	 Specifies VDMA channel transactions that are flushed and channel states that are reset on frame sync after certain DMA internal error detection. 0 = No flush/reset on frame sync 1 = Flush/reset on frame sync <i>Note:</i> This parameter is valid only when C_USE_FSYNC=1.
C_FAMILY	virtex6, spartan6, virtex7, kintex7, artix7	virtex6	string	Specifies the target FPGA family

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_INCLUDE_INTERNAL_ GENLOCK	0	0, 1	Integer	 Include or exclude an internal Genlock bus with MUX. Allows internal routing of MM2S and S2MM Genlock buses. 0 = Exclude internal Genlock bus 1 = Include internal Genlock bus
C_MM2S_SOF_ENABLE	0	0, 1	Integer	Enables SOF generation for MM2S channel. SOF pulse driven on m_axis_mm2s_tuser(0) coincident with first pixel of the first line for each frame.
C_S2MM_SOF_ENABLE	0	0, 1	Integer	Enables SOF detection for S2MM channel. SOF pulse received on s_axis_s2mm_tuser(0) coincident with the first pixel of first line for each frame.
	Scatter	r Gather Eng	ine Parameters	
C_INCLUDE_SG	0, 1	0	integer	 Include or exclude the Scatter Gather Engine. When excluded, all unused ports are tied off or driven to zero. This also maps the video specific register to the AXI4-Lite Control interface. 0 = Exclude SG Engine
C_M_AXI_SG_DATA_WIDTH	32	32	integer	 1 = Include SG Engine Data width of AXI Scatter Gather Engine
C_M_AXI_SG_ADDR_WIDTH	32	32	integer	Address width of AXI Scatter Gather Engine
	Memory	y Map to Str	eam Parameters	
C_INCLUDE_MM2S	0,1	1	integer	 Include or exclude the Memory Map to Stream channel. When excluded, all unused ports are tied off or driven to zero. This also excludes MM2S AXI Control Stream. 0 = Exclude MM2S
C_INCLUDE_MM2S_SF	0,1	1	integer	 1 = Include MM2S Include or exclude the Memory Map to Stream channel Store-And-Forward. 0 = Exclude Store-And-Forward 1 = Include Store-And-Forward

Table 4-2:	AXI VDMA	Design Parameters	Description (Cont'd)
------------	----------	--------------------------	----------------------

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_MM2S_GENLOCK_MODE	0, 1	0	integer	 Specifies the Genlock mode for the MM2S Channel. Master mode specifies that the Video DMA operates as the Genlock Master. Slave mode specifies that the Video DMA operate as a Genlock Slave. 0 = Master Mode 1 = Slave Mode
C_MM2S_GENLOCK_NUM_ MASTERS	1-16	1	integer	Specifies the number of Masters to which the Slave can synchronize. A register is used to dynamically specify which master is in control at any given time. Note: This parameter is only valid in Genlock Slave mode (C_MM2S_GENLOCK_MODE = 1)
C_MM2S_GENLOCK_ REPEAT_EN	0	0, 1	Integer	 Specifies if an errored frame is repeated on the next frame sync or if the frame is advanced to the next frame. 0 = Frame is advanced 1 = Frame is repeated <i>Note:</i> This parameter is only valid if C_MM2S_GENLOCK_MODE = 0, C_USE_FSYNC = 1, and C_FLUSH_ON_FSYNC = 1.
C_INCLUDE_MM2S_DRE	0, 1	0	integer	 Include or exclude the Memory Map to Stream channel Data Realignment Engine. 0 = Exclude DRE 1 = Include DRE Note: DRE support not available for AXI4-Stream data widths of 128, 256, 512 bits and 1024 bits.
C_MM2S_LINEBUFFER_DEPTH	0 - 65536	128	integer	Depth of Line Buffer FIFO. Depth specified in bytes. Valid minimum depth, excluding 0, equals C_M_AXIS_MM2S_TDATA_WIDTH /8, must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is the nearest upper power of 2 value. See C_MM2S_LINEBUFFER_DEPTH in Parameter Descriptions for more details.

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_MM2S_LINEBUFFER_ THRESH	1 - 65536	4	integer	Almost Empty Threshold. Threshold point at which the MM2S line buffer almost empty flag asserts high. Threshold specified in bytes and must be C_M_AXIS_MM2S_TDATA_WIDTH /8 resolution. That is, for a Data Width of 32-bits valid threshold settings are 4, 8, 12, 16, 20, and so on. Note: If C_M_AXIS_MM2S_TDATA_WIDTH is a non-power of 2, the line buffer threshold value should be calculated based on the nearest upper power of 2 value. For example if C_M_AXIS_MM2S_TDATA_WIDTH = 24, threshold values should be calculated based on the nearest upper power of 2. That is, C_M_AXIS_MM2S_TDATA_WIDTH = 32. See
			C_MM2S_LINEBUFFER_THRESH in Parameter Descriptions for more details.	
C_M_AXI_MM2S_ADDR_ WIDTH	32	32	integer	Address width of AXI4 Memory Map on the Memory Map to Stream interface
C_M_AXI_MM2S_DATA_ WIDTH	32, 64,128, 256, 512, 1024	32	integer	Data width of AXI4 Memory Map on the Memory Map to Stream Interface
C_M_AXIS_MM2S_TDATA_ WIDTH	8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, 1024	32	integer	Data width of AXI4-Stream on the Stream to Memory Map Interface. Width must be less than or equal to C_M_AXI_MM2S_DATA_WIDTH.
C_MM2S_MAX_BURST_ LENGTH	16, 32, 64, 128, 256	16	integer	Maximum burst length in data beats per burst request on Memory Map Read interface

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
	Stream	to Memory	Map Parameters	
C_INCLUDE_S2MM	0, 1	1	integer	 Include or exclude the Stream to Memory Map. When excluded, all unused ports are tied off or driven to zero. This also excludes S2MM AXI Status Stream. 0 = Exclude S2MM 1 = Include S2MM
C_INCLUDE_S2MM_SF	0, 1	1	integer	 Include or exclude the Stream to Memory Map channel Store-And-Forward. 0 = Exclude Store-And-Forward 1 = Include Store-And-Forward
C_S2MM_GENLOCK_MODE	0, 1	0	integer	 Specifies the Genlock mode for the S2MM Channel. Master mode specifies that the Video DMA operate as the Genlock Master. Slave mode specifies that the Video DMA operate as a Genlock Slave. 0 = Master Mode 1 = Slave Mode
C_S2MM_GENLOCK_NUM_ MASTERS	1 - 16	1	integer	Specifies the number of Masters to which the slave can synchronize. A register is used to dynamically specify which master is in control at any given time. Note: This parameter is only valid in Genlock Slave mode (C_S2MM_GENLOCK_MODE = 1).
C_S2MM_GENLOCK_ REPEAT_EN	0	0, 1	Integer	 Specifies if an errored frame is repeated on the next frame sync or if the frame is advanced to the next frame 0 = Frame is advanced 1 = Frame is repeated <i>Note:</i> This parameter is only valid if C_S2MM_GENLOCK_MODE = 0, C_USE_FSYNC = 1, and C_FLUSH_ON_FSYNC = 1

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_INCLUDE_S2MM_DRE	0, 1	0	integer	 Include or exclude the Stream to Memory Map channel Data Realignment Engine. 0 = Exclude DRE 1 = Include DRE <i>Note:</i> DRE support is not available for AXI4-Stream data widths of 128, 256, 512 bits, and 1024 bits.
C_S2MM_LINEBUFFER_DEPTH	0 - 65536	128	integer	Depth of Line Buffer FIFO. Depth specified in bytes. Valid minimum depth, excluding 0, equals C_S_AXIS_S2MM_TDATA_WIDTH/ 8, and must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is the nearest upper power of 2 value. See C_S2MM_LINEBUFFER_DEPTH in Parameter Descriptions for more details.
C_S2MM_LINEBUFFER_ THRESH	1 - 65536	4	integer	Almost Full Threshold. Threshold point at which S2MM line buffer almost full flag asserts high. Threshold specified in bytes and must be C_S_AXIS_S2MM_TDATA_WIDTH/ 8 resolution. That is, for a Data Width of 32-bits valid threshold settings would be 4, 8, 12, 16, 20, and so on. Note: If C_S_AXIS_S2MM_TDATA_WIDTH is a non-power of 2, the line buffer threshold value should be calculated based on the nearest upper power of 2 value. For example if C_S_AXIS_S2MM_TDATA_WIDTH = 24, the threshold values should be calculated based on nearest upper power of 2. That is, C_S_AXIS_S2MM_TDATA_WIDTH = 32. See C_S2MM_LINEBUFFER_THRESH in Parameter Descriptions for more details.
C_M_AXI_S2MM_ADDR_ WIDTH	32	32	integer	Address width of AXI4 Memory Map on the Stream to Memory Map interface
C_M_AXI_S2MM_DATA_ WIDTH	32, 64, 128, 256, 512, 1024	32	integer	Data width of AXI4 Memory Map on the Stream to Memory Map Interface

Parameter Name	Allowable Values	Default Values	VHDL Type	Feature/Description
C_S_AXIS_S2MM_TDATA_ WIDTH	8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, 1024	32	integer	Data width of AXI4-Stream on the Stream to Memory Map Interface. Width must be less than or equal to C_M_AXI_S2MM_DATA_WIDTH.
C_S2MM_MAX_BURST_ LENGTH	16, 32, 64, 128, 256	16	integer	Maximum burst length in data beats per burst request on Memory Map Write interface.

Table 4-3: AXI Interconnect Parameters^a

Non-HDL Parameter (mpd only)	Allowable Values	Default Values	Description
C_BASEADDR	0x00000000 - 0xffffffff	0xffffffff	Base Address for AXI4-Lite Register interface. Used by AXI Interconnect address decode
C_HIGHADDR	0x00000000 - 0xffffffff	0x00000000	High Address for AXI4-Lite Register interface. Used by AXI Interconnect address decode
C_INTERCONNECT_M_AXI_MM2S_ READ_ISSUING	1, 2, 4	4	This parameter sets the number of outstanding read requests that the AXI Interconnect accepts from the AXI DMA MM2S Read Master. This parameter configures the AXI Interconnect slave port connected to the MM2S Read Master of AXI VDMA.
C_INTERCONNECT_M_AXI_S2MM_ WRITE_ISSUING	1, 2, 4	4	This parameter sets the number of outstanding write requests that the AXI Interconnect accepts from the AXI DMA S2MM Write Master. This parameter configures the AXI Interconnect slave port connected to the S2MM Write Master of AXI VDMA.
C_INTERCONNECT_M_AXI_MM2S_ READ_FIFO_DEPTH	0, 32, 512	0	This parameters sets the read data FIFO depth (in elements) for AXI DMA MM2S Read Master. This parameter configures the AXI Interconnect slave port connected to the MM2S Read Master of AXI VDMA.
C_INTERCONNECT_M_AXI_S2MM_ WRITE_FIFO_DEPTH	0, 32, 512	0	This parameters sets the write data FIFO depth (in elements) for the AXI DMA S2MM Write Master. This parameter configures the AXI Interconnect slave port connected to the S2MM Write Master of AXI VDMA.

a. The parameters listed here are controllable by user. There are also other parameters that are always constant.

Allowable Parameter Combinations

Table 4-4: Allowable Parameter Combination

Parameter Name	Affects Parameter	Relationship Description	
	C_INCLUDE_MM2S_DRE C_INCLUDE_MM2S_SF

	MASTERS	Affected Parameter is ignored when C_MM2S_GENLOCK_MODE = 0.	
	C_MM2S_GENLOCK_REPEAT_EN		
C_S2MM_GENLOCK_MODE	C_S2MM_GENLOCK_NUM_	Affected Parameter is ignored when	
	MASTERS C S2MM GENLOCK REPEAT EN	$C_MM2S_GENLOCK_MODE = 0.$	
	C_32IVIIVI_GEINLOCK_KEFEAI_EN		
C_M_AXI_MM2S_DATA_	C_M_AXIS_MM2S_TDATA_WIDTH	Affected Parameter must be less than or equal to	
WIDTH		C_M_AXI_MM2S_DATA_WIDTH.	

Table 4-4:	Allowable Pa	arameter	Combination	(Cont'd)
------------	--------------	----------	-------------	----------

Parameter Name	Affects Parameter	Relationship Description
C_M_AXI_S2MM_DATA_ WIDTH	C_S_AXIS_S2MM_TDATA_WIDTH	Affected Parameter must be less than or equal to C_M_AXI_S2MM_DATA_WIDTH.
C_MM2S_LINEBUFFER_DEPTH and C_M_AXIS_MM2S_TDATA_ WIDTH	C_MM2S_LINEBUFFER_THRESH	Affected Parameter is ignored when C_MM2S_LINEBUFFER_DEPTH = 0. See Parameter Descriptions for valid minimum and maximum threshold values.
C_S2MM_LINEBUFFER_DEPTH and C_S_AXIS_S2MM_TDATA_ WIDTH	C_S2MM_LINEBUFFER_THRESH	Affected Parameter is ignored when C_S2MM_LINEBUFFER_DEPTH = 0. See Parameter Descriptions for valid minimum and maximum threshold values.
C_INCLUDE_SG	C_ENABLE_VIDPRMTR_READS C_M_AXI_SG_ADDR_WIDTH C_M_AXI_SG_DATA_WIDTH	C_ENABLE_VIDPRMTR_READS is active when C_INCLUDE_SG = 0. C_M_AXI_SG_ADDR_WIDTH and C_M_AXI_SG_DATA_WIDTH are ignored when C_INCLUDE_SG = 0.
C_PRMRY_IS_ACLK_ASYNC	C_MM2S_LINEBUFFER_THRESH C_S2MM_LINEBUFFER_THRESH	If C_PRMRY_IS_ACLK_ASYNC is set to 1, the line buffers are included with a minimum depth of 512 elements regardless of C_MM2S_LINEBUFFER_THRESH/ C_S2MM_LINEBUFFER_THRESH.
C_USE_FSYNC	C_FLUSH_ON_FSYNC C_MM2S_SOF_ENABLE C_S2MM_SOF_ENABLE C_MM2S_GENLOCK_REPEAT_ ENABLE C_S2MM_GENLOCK_REPEAT_ ENABLE	Affected parameters are ignored when C_USE_FSYNC = 0.
C_MM2S_GENLOCK_MODE and C_S2MM_GENLOCK_MODE	C_INCLUDE_INTERNAL_GENLOCK	Affected parameter is ignored when C_MM2S_GENLOCK_MODE = C_S2MM_GENLOCK_MODE, that is, when both channels are configured as either Masters or Slaves.

Parameter Descriptions

C_PRMRY_IS_ACLK_ASYNC

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- Definition: 0 = s_axi_lite_aclk, m_axi_sg_aclk, m_axi_mm2s_aclk, m_axis_mm2s_aclk, m_axi_s2mm_aclk and s_axis_s2mm_aclk are synchronous to each other; 1 = s_axi_lite_aclk, m_axi_sg_aclk, m_axi_mm2s_aclk, m_axis_mm2s_aclk, m_axi_s2mm_aclk and s_axis_s2mm_aclk are asynchronous to each other.
- **Description:** Provides ability to operate the primary datapath asynchronously to the AXI4-Lite and Scatter Gather Engine. This is used for applications where there is a requirement to operate the primary datapath at high frequencies, but this same high frequency requirement is not required for reading and writing control registers or for fetching and updating descriptors. In some cases, this allows for easier placement and timing closure at system build time. The EDK tool suite assigns this parameter based on the clock sources for s_axi_lite_aclk, m_axi_sg_aclk, m_axi_mm2s_aclk, m_axis_mm2s_aclk, m_axi_s2mm_aclk and s_axis_s2mm_aclk.

C_DLYTMR_RESOLUTION

- Type: Integer
- Allowed Values: 1 to 100,000 (default = 125)
- **Definition:** Interrupt Delay Timer Resolution
- **Description:** This integer parameter is used to set the resolution of the Interrupt Delay Timer. Values specify the number of m_axi_sg_aclk clock cycles (when C_INCLUDE_SG=1) or s_axi_lite_aclk clock cycles (when C_INCLUDE_SG = 0) between each tick of the delay timer.

C_NUM_FSTORES

- Type: Integer
- Allowed Values: 1 to 32 (default = 3)
- **Definition:** Maximum number of frame stores
- **Description:** This integer parameter is used to define the maximum number of frame storage locations to be processed by the AXI VDMA. For Scatter Gather Mode (C_INCLUDE_SG = 1), this parameter also defines the maximum number of Scatter Gather descriptors per channel in the descriptor chain required to initialize the AXI VDMA. For Register Direct Mode (C_INCLUDE_SG = 0), this parameter defines the maximum number of video Start Address Registers for each channel. The actual number of frame store locations used, per channel, is set by register write to MM2S_FRM_STORE (offset 0x18) or S2MM_FRM_STORE (offset 0x48) register for the associated channel.

C_USE_FSYNC

- Type: Integer
- Allowed Values: 0, 1 (default = 0)
- **Definition:** 0 = Free run mode, 1 = Frame sync mode
- **Description:** This integer parameter is used to set the synchronization mode of AXI VDMA. When in free mode, the AXI VDMA transfers data as quickly as it is able to. When in frame sync mode, the AXI VDMA transfers data starting with the falling edge of each mm2s_fsync or s2mm_fsync for the associated channel.

C_ENABLE_VIDPRMTR_READS

- Type: Integer
- Allowed Values: 0, 1 (default =1)
- **Definition:** 0 = Disable Video Parameter Reads, 1 = Enable Video Parameter Reads
- **Description:** This integer parameter is used to enable the read access to the video parameters by the s_axi_lite interface when configured for Register Direct Mode. Disabling the video parameter register reads reduces FPGA resource utilization.

C_INCLUDE_INTERNAL_GENLOCK

- Type: Integer
- Allowed Values: 0,1
- **Definition:** 0 = Exclude internal Genlock bus, 1 = Include internal Genlock bus
- **Description**: Include or exclude an internal Genlock bus. It allows internal routing of MM2S and S2MM Genlock buses without having it connected outside the core.

C_MM2S_SOF_ENABLE

- Type: Integer
- Allowed Values: 0,1
- **Definition**: 0 = Disables SOF generation on m_axis_mm2s_tuser(0), 1 = Enables SOF generation on m_axis_mm2s_tuser(0)
- **Description**: SOF pulse is driven on m_axis_mm2s_tuser(0) coincident with first pixel of the first line for each frame.

C_S2MM_SOF_ENABLE

- Type: Integer
- Allowed Values: 0,1
- **Definition**: 0 = Disables SOF detection on s_axis_s2mm_tuser(0), 1 = Enables SOF detection on s_axis_s2mm_tuser(0)
- **Description**: This setting along with FsyncSrcSelect = 10, enables SOF pulse detection on m_axis_mm2s_tuser(0). SOF pulse is coincident with the first pixel of the first line for each frame.

C_FLUSH_ON_FSYNC

- Type: Integer
- Allowed Values: 0,1 (default = 1)
- **Definition:** 0 = No flush/reset on frame sync, 1 = Flush/reset on frame sync
- **Description:** Specifies when VDMA channel transactions are flushed and channel states are reset on frame sync.

C_S_AXI_LITE_ADDR_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- Definition: Address bus width of attached AXI on the AXI4-Lite interface
- **Description:** This integer parameter is used by the AXI4-Lite interface to size the AXI read and write address bus related components within the Lite interface. The EDK tool suite assigns this parameter a fixed value of 32.

C_S_AXI_LITE_DATA_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- Definition: Data bus width of attached AXI on the AXI4-Lite interface
- **Description:** This integer parameter is used by the AXI4-Lite interface to size the AXI read and write data bus related components within the Lite interface. The EDK tool suite assigns this parameter a fixed value of 32.

C_INCLUDE_SG

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- **Definition:** 0 = Exclude SG Engine; 1 = Include SG Engine
- **Description:** Include or exclude Scatter Gather Engine. Setting this parameter to 0 causes all output ports for the Scatter Gather engine to be tied to zero and all of the input ports to be left open. Excluding the Scatter Gather engine configures the AXI VDMA for Register Direct Mode.

C_M_AXI_SG_DATA_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- Definition: Data bus width of attached AXI on the AXI Scatter Gather interface
- **Description:** This integer parameter is used by the AXI Scatter Gather interface to size the AXI read data bus related components within the Scatter Gather Engine. The EDK tool suite assigns this parameter a fixed value of 32.

C_M_AXI_SG_ADDR_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- **Definition:** Address bus width of attached AXI on the AXI Scatter Gather interface
- **Description:** This integer parameter is used by the AXI Scatter Gather interface to size the AXI read address bus related components within the Scatter Gather Engine. The EDK tool suite assigns this parameter a fixed value of 32.

C_INCLUDE_MM2S

- Type: Integer
- Allowed Values: 0,1 (default = 1)
- **Definition:** 0 = Exclude MM2S Channel; 1 = Include MM2S Channel
- **Description:** Include or exclude MM2S Channel. Setting this parameter to 0 causes all output ports for the MM2S channel to be tied to zero and all of the input ports for the respective channel to be left open.

Note: Setting both C_INCLUDE_MM2S = 0 and C_INCLUDE_S2MM = 0 disables all logic within the AXI VDMA and is not a valid configuration.

C_INCLUDE_S2MM

- Type: Integer
- **Allowed Values:** 0,1 (default = 1)
- **Definition:** 0 = Exclude S2MM Channel; 1 = Include S2MM Channel
- **Description:** Include or exclude S2MM Channel. Setting this parameter to 0 causes all output ports for the S2MM channel to be tied to zero, and all of the input ports for the respective channel to be left open.

Note: Setting both C_INCLUDE_MM2S = 0 and C_INCLUDE_S2MM = 0 disables all logic within the AXI VDMA and is not a valid configuration.

C_INCLUDE_MM2S_DRE

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- **Definition:** 0 = Exclude MM2S Data Realignment Engine; 1 = Include MM2S Data Realignment Engine
- **Description:** Include or exclude MM2S Data Realignment Engine. For use cases where all transfers are C_M_AXI_MM2S_DATA_WIDTH aligned, this parameter can be set to 0 to exclude DRE-saving FPGA resources. Setting this parameter to 1 allows data realignment to the byte (8 bits) level on the primary memory map datapaths. For the MM2S channel, vertical size (vsize) number of video lines each horizontal size (hsize) bytes long and spaced stride bytes apart (stride is number of bytes between first pixel of each line) are read from memory.

For the case where C_INCLUDE_MM2S_DRE = 1, data reads can start from any Start Address byte offset, be of any horizontal size and stride value and the read data are aligned such that the first byte read is the first valid byte out on the AXI4-Stream.

For the case where C_IN CLUDE_MM2S_DRE = 0, the Start Address must be aligned to multiples of C_M_AXI_MM2S_DATA_WIDTH bytes. Also Horizontal Size and Stride must be specified in even multiples of C_M_AXI_MM2S_DATA_WIDTH bytes.

For example, if C_M_AXI_MM2S_DATA_WIDTH = 32, data are aligned if the Start Address at word offsets (32-bit offset), that is, 0x0, 0x4, 0x8, 0xC, and so on. Horizontal Size is 0x4, 0x8, 0xC and so on. Stride is 0x4, 0x8, 0xC, and so on.

If C_M_AXI_MM2S_DATA_WIDTH = 64, data are aligned if the Start Address is at double-word offsets (64-bit offsets), that is, 0x0, 0x8, 0x10, 0x18, and so on. Horizontal Size and Stride are at 0x4, 0x8, 0xC, and so on.

Note: If DRE is disabled (C_INCLUDE_MM2S_DRE = 0), unaligned start addresses, hsizes, or strides, are not supported. Having an unaligned Start Address, HSize, and/or Stride results in undefined behavior.

Note: DRE support is only available for AXI4-Stream data width setting of 64-bits and less.

C_INCLUDE_S2MM_DRE

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- **Definition:** 0 = Exclude S2MM Data Realignment Engine, 1 = Include S2MM Data Realignment Engine
- **Description:** Include or exclude S2MM Data Realignment Engine. For use cases where all transfers are C_M_AXI_S2MM_DATA_WIDTH aligned, this parameter can be set to 0 to exclude DRE-saving FPGA resources. Setting this parameter to 1 allows data realignment to the byte (8 bits) level on the primary memory map datapaths. For the S2MM channel, the vertical size (vsize) number of video lines each horizontal size (hsize) bytes long and spaced stride bytes apart (stride is number of bytes between first pixel of each line) are written to memory.

For the case where C_INCLUDE_S2MM_DRE = 1, data writes can start from any Start Address byte offset, be of any horizontal size and stride value and the write data are aligned such that first valid byte in on the AXI4-Stream is the byte written to the memory location specified by the Start Address, Hsize, and Stride.

For the case where C_IN CLUDE_S2MM_DRE = 0, then the Start Address must be aligned to multiples of C_M_AXI_S2MM_DATA_WIDTH bytes. Also Horizontal Size and Stride must be specified in even multiples of C_M_AXI_S2MM_DATA_WIDTH bytes. For example, if C_M_AXI_S2MM_DATA_WIDTH = 32, data are aligned if the Start Address at word offsets (32-bit offset), that is 0x0, 0x4, 0x8, 0xC, and so on, Horizontal Size is 0x4, 0x8, 0xC and so on, Stride is 0x4, 0x8, 0xC, and so on.

If C_M_AXI_S2MM_DATA_WIDTH = 64, data are aligned if the Start Address is at double-word offsets (64-bit offsets), that is, 0x0, 0x8, 0x10, 0x18, and so on; Horizontal Size and Stride are at 0x4, 0x8, 0xC, and so on.

Note: If DRE is disabled (C_INCLUDE_S2MM_DRE = 0), unaligned start addresses, hsizes, or strides, are not supported. Having an unaligned Start Address, HSize, and/or Stride results in undefined behavior. DRE support is only available for AXI4-Stream data width setting of 64-bits and under.

C_INCLUDE_MM2S_SF

- Type: Integer
- Allowed Values: 0,1 (default = 1)
- **Definition:** 0 = Exclude MM2S Store-And-Forward; 1 = Include MM2S Store-And-Forward
- **Description:** Include or exclude MM2S Store-And-Forward buffer. When included, a Store-And-Forward buffer and manager are instantiated in AXI VDMA preventing the MM2S channel from requesting more read data than can be held in the Store-And-Forward buffer. This is for use cases where the target Video IP cannot accept all of the stream data transmitted by AXI VDMA MM2S channel. After the Store-And-Forward buffer is full, the AXI VDMA MM2S channel does not issue any more read requests preventing the AXI4 Slave from being tied up.

If both the MM2S Line Buffer is included and the Store-And-Forward buffer is included then m_axis_mm2s_tvalid does not assert high until the set line buffer threshold, C_MM2S_LINEBUFFER_THRESH, is met.

When excluded, no Store-And-Forward buffer is instantiated and as soon as data is read by AXI VDMA, m_axis_mm2s_tvalid asserts. Also read requests by AXI VDMA are made as quickly as possible.

Note: If both the MM2S Line Buffer is included (C_MM2S_LINEBUFFER_DEPTH \neq 0) and the Store-And-Forward Buffer is included (C_INCLUDE_MM2S_SF = 1), both features share a single buffer saving block RAM resources. The depth of the buffer is set to the maximum of C_MM2S_LINEBUFFER_DEPTH or the necessary depth as required by Store-And-Forward, which is the depth that is the next power of two greater than 6 x C_MM2S_MAX_BURST_LENGTH.

C_INCLUDE_S2MM_SF

- Type: Integer
- Allowed Values: 0,1 (default = 1)
- **Definition:** 0 = Exclude S2MM Store-And-Forward; 1 = Include S2MM Store-And-Forward
- **Description:** Include or exclude S2MM Store-And-Forward buffer. When included, a Store-And-Forward buffer and manager are instantiated in the AXI VDMA preventing the S2MM channel from issuing write requests until it has enough data to fulfill the complete requested write. This is for use cases where the source Video IP cannot deliver a contiguous stream of data to be received by the AXI VDMA S2MM channel. After the Store-And-Forward buffer has enough data to complete a write, the AXI VDMA S2MM channel issues a write request. If there is not enough data for the write to complete, then no request is made preventing the AXI4 Slave from being tied up. When excluded, no Store-And-Forward buffer is instantiated and write requests by AXI VDMA are made as quickly as possible.

Note: If both the S2MM Line Buffer is included (C_S2MM_LINEBUFFER_DEPTH \neq 0) and the Store-And-Forward Buffer is included (C_INCLUDE_S2MM_SF = 1), both features share a single buffer, saving block RAM resources. The depth of the buffer is set to the maximum of C_S2MM_LINEBUFFER_DEPTH or the necessary depth as required by Store-And-Forward, which is the depth that is the next power of two greater than 6 x C_S2MM_MAX_BURST_LENGTH.

C_S2MM_GENLOCK_MODE

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- **Definition:** 0 = Genlock Master Mode, 1 = Genlock Slave Mode
- Description: This integer values sets the S2MM channel Genlock synchronization mode. Master mode specifies that the S2MM VDMA channel operates at the Genlock Master. In Master mode, frames are not dropped or repeated. The current master frame being worked on by the S2MM channel is specified on s2mm_frm_ptr_out. Slave mode specifies that the S2MM VDMA channel operates as a Genlock Slave. Genlock slaves automatically drop and repeat frames based on the master and slave frame rates. The Genlock slave looks at the vector slice of s2mm_frm_ptr_in as specified in S2MM DMACR Write Pointer Number field (DMACR.WrPntrNmbr bits 11 downto 8) to determine which frame the master is working on and operates Frame Delay behind the master.

C_MM2S_GENLOCK_MODE

- Type: Integer
- Allowed Values: 0,1 (default = 0)
- **Definition:** 0 = Genlock Master Mode, 1 = Genlock Slave Mode
- **Description**: This integer parameter sets the MM2S Channel Genlock synchronization mode. Master mode specifies that the MM2S VDMA channel operates at the Genlock Master. In Master mode, frames are not dropped or repeated. The current master frame being worked on by the MM2S channel is specified on mm2s_frm_ptr_out. Slave mode specifies that the MM2S VDMA channel operates as a Genlock Slave. Genlock slaves automatically drop and repeat frames based on the master and slave frame rates. The Genlock slave looks at the vector slice of mm2s_frm_ptr_in as specified in the MM2S DMACR Read Pointer Number field (DMACR.RdPntrNmbr bits 11 downto 8) to determine which frame the master is working on and operates the Frame Delay behind the master.

C_MM2S_GENLOCK_NUM_MASTERS

- Type: Integer
- Allowed Values: 1 to 16(default = 1)
- Definition: Number of masters to which the slave synchronizes operations.
- **Description**: This integer parameter specifies to the Genlock slave the total number of masters to synchronize operations to. This parameter also specifies the vector width of the mm2s_frm_ptr_in port, where each master requires 5 bits on the mm2s_frm_ptr_in vector. Therefore the width of the mm2s_frm_ptr_in port is 6* C_MM2S_GENLOCK_NUM_MASTERS.

Note: This parameter is only valid for Genlock Slave mode (C_MM2S_GENLOCK_MODE = 1) and is ignored in Genlock Master mode.

C_S2MM_GENLOCK_NUM_MASTERS

- Type: Integer
- Allowed Values: 1 to 16 (default = 1)
- **Definition:** Number of masters to which the slave synchronizes operations.
- **Description**: This integer parameter specifies to the Genlock slave the total number of masters to synchronize operations to. This parameter also specifies the vector width of the s2mm_frm_ptr_in port, where each master requires 5 bits on the mm2s_frm_ptr_in vector. Therefore, the width of the s2mm_frm_ptr_in port is 6* C_S2MM_GENLOCK_NUM_MASTERS.

Note: This parameter is only valid for Genlock Slave mode (C_S2MM_GENLOCK_MODE = 1) and is ignored in Genlock Master mode.

C_MM2S_GENLOCK_REPEAT_EN

- Type: Integer
- **Allowed Values:** 0 to 1(default = 0)
- **Definition:** 0 = Frame is advanced, 1 = Frame is repeated
- **Description**: Specifies if an errored frame is repeated on the next frame sync or if the frame is advanced to the next frame

Note: This parameter is only valid for Genlock Slave mode (C_MM2S_GENLOCK_MODE = 0) and is ignored in Genlock Master mode.

C_S2MM_GENLOCK_REPEAT_EN

- Type: Integer
- **Allowed Values:** 0 to 1(default = 0)
- **Definition:** 0 = Frame is advanced, 1 = Frame is repeated
- **Description**: Specifies if an errored frame is repeated on the next frame sync or if the frame is advanced to the next frame.

This parameter is only valid for Genlock Slave mode (C_S2MM_GENLOCK_MODE = 0) and is ignored in Genlock Master mode.

C_S_AXI_MM2S_ADDR_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- **Definition:** Address bus width of attached AXI on the AXI MM2S Memory Map Read interface
- **Description:** This integer parameter is used by the MM2S interface to size the AXI read address bus-related components within the MM2S Channel. The EDK tool suite assigns this parameter a fixed value of 32.

C_M_AXI_MM2S_DATA_WIDTH

- Type: Integer
- Allowed Values: 32, 64, 128, 256, 512, 1024 (default = 32)
- **Definition:** Data bus width of attached AXI on the AXI MM2S Memory Map Read interface
- **Description:** This integer parameter is used by the MM2S interface to size the AXI read data bus related components within the MM2S Channel. The EDK tools ensure correct sizing of the AXI data width based on EDK system configuration.

C_M_AXIS_MM2S_TDATA_WIDTH

- Type: Integer
- Allowed Values: 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768,1024 (default = 32)
- **Definition:** Data bus width of attached AXI on the AXI MM2S Master Stream interface
- Description: This integer parameter is used by the MM2S interface to size the AXI Master Stream data bus-related components within the MM2S Channel.
 Note: This parameter must be set less than or equal to C_M_AXI_MM2S_DATA_WIDTH.

C_M_AXIS_MM2S_TUSER_BITS

- Type: Integer
- Allowed Values: 1
- Definition: 1 = Bit width of TUSER on MM2S interface is 1.

C_M_AXI_S2MM_ADDR_WIDTH

- Type: Integer
- Allowed Values: 32 (default = 32)
- **Definition:** Address bus width of attached AXI on the AXI S2MM Memory Map Write interface
- **Description:** This integer parameter is used by the S2MM interface to size the AXI write address bus-related components within the S2MM Channel. The EDK tool suite assigns this parameter a fixed value of 32.

C_M_AXI_S2MM_DATA_WIDTH

- Type: Integer
- Allowed Values: 32, 64, 128, 256, 512, 1024 (default = 32)
- **Definition:** Data bus width of attached AXI on the AXI S2MM Memory Map Write interface
- **Description:** This integer parameter is used by the S2MM interface to size the AXI write data bus-related components within the S2MM channel. The EDK tools ensure correct sizing of the AXI data width based on the EDK system configuration.

C_S_AXIS_S2MM_TDATA_WIDTH

- Type: Integer
- Allowed Values: 8, 16, 24, 32, 48, 64, 96, 128, 192, 256, 384, 512, 768, 1024 (default = 32)
- Definition: Data bus width of attached AXI on the AXI S2MM Slave Stream interface
- **Description:** This integer parameter is used by the S2MM interface to size the AXI Slave Stream data bus related components within the S2MM Channel. *Note:* This parameter must be set less than or equal to C_M_AXI_S2MM_DATA_WIDTH.

C_S_AXIS_S2MM_TUSER_BITS

- Type: Integer
- Allowed Values: 1
- Definition: 1 = Bit width of TUSER on S2MM interface is 1.

C_MM2S_MAX_BURST_LENGTH

- Type: Integer
- Allowed Values: 16, 32, 64, 128, 256 (default = 16)
- **Definition:** MM2S maximum burst length in data beats
- **Description:** Maximum burst length of the MM2S memory map interface. This parameter sets the granularity of burst partitioning. For example, if the burst length is set to 16, the maximum burst on the memory map interface will be 16 data beats. Smaller values reduce throughput but result in less impact on the AXI infrastructure. Larger values increase throughput but result in a greater impact on the AXI infrastructure.

C_S2MM_MAX_BURST_LENGTH

- Type: Integer
- Allowed Values: 16, 32, 64, 128, 256 (default = 16)
- Definition: S2MM maximum burst length in data beats
- **Description:** Maximum burst length of the S2MM memory map interface. This parameter sets the granularity of burst partitioning. For example, if the burst length is set to 16, the maximum burst on the memory map interface is 16 data beats. Smaller values reduce throughput but result in less impact on the AXI infrastructure. Larger values increase throughput but result in a greater impact on the AXI infrastructure.

C_MM2S_LINEBUFFER_DEPTH

- Type: Integer
- Allowed Values: 0, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384, 32768, 65536 (default = 128)
- Definition: MM2S line buffer depth
- **Description:** Depth of Line Buffer FIFO. Depth specified in bytes. Depth parameter must be a power of 2 value, that is, 1, 2, 4, 8, 16,...1024, 2048, and so on. The valid minimum depth, excluding 0, equals C_M_AXIS_MM2S_TDATA_WIDTH/8; it must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is the nearest upper power of 2 value.

Stream Data Width	Allowed Values
8	1, 2, 4,65536
16	2, 4, 8,65536
24, 32	4, 8, 16,65536
48, 64	8, 16, 32,65536
96, 128	16, 32, 64,65536
192, 256	32, 64, 128,65536
384, 512	64, 128, 256,65536
768, 1024	128, 256, 512,65536

Note: A value of zero will exclude the line buffer.

C_S2MM_LINEBUFFER_DEPTH

- Type: Integer
- Allowed Values: 0, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384, 32768, 65536 (default = 128)
- **Definition:** S2MM line buffer depth
- **Description:** Depth of Line Buffer FIFO. Depth specified in bytes. Depth parameter must be a power of 2 value, that is, 1, 2, 4, 8, 16,...1024, 2048, and so on. The valid minimum depth, excluding 0, equals C_S_AXIS_S2MM_TDATA_WIDTH/8; it must always be a power of 2 value. In case this division produces a non-power of 2 value, the allowed minimum depth is the nearest upper power of 2 value.

Stream Data Width	Allowed Values
8	1, 2, 4,65536
16	2, 4, 8,65536
24, 32	4, 8, 16,65536
48, 64	8, 16, 32,65536
96, 128	16, 32, 64,65536
192, 256	32, 64, 128,65536
384, 512	64, 128, 256,65536
768, 1024	128, 256, 512,65536

Note: A value of zero will exclude the line buffer.

www.xilinx.com

C_MM2S_LINEBUFFER_THRESH

- Type: Integer
- Allowed Values: 1 to 65536 (default = 4)
- Definition: MM2S line buffer almost empty threshold in bytes
- **Description:** Almost Empty Threshold. Sets the default threshold point at which the MM2S line buffer almost empty flag asserts high. The threshold can be modified dynamically during run time by writing to the MM2S_THRESHOLD register. The threshold is specified in bytes and must be multiple of

C_M_AXIS_MM2S_TDATA_WIDTH/8. If C_M_AXIS_MM2S_TDATA_WIDTH is a non power of 2, the line buffer threshold value should be calculated based on the nearest upper power of 2 value.

For example if C_M_AXIS_MM2S_TDATA_WIDTH = 24, the threshold values should be calculated based on nearest upper power of 2. That is, C_M_AXIS_MM2S_TDATA_WIDTH = 32.

The following table illustrates the stream data width and its corresponding allowed line buffer threshold values

Stream Data Width	Allowed Values
8	1, 2, 3,
16	2, 4, 6,
24, 32	4, 8, 12,
48, 64	8, 16, 24,
96, 128	16, 32, 48,
192, 256	32, 64, 96,
384, 512	64, 128, 192,
768, 1024	128, 256, 384,

On power up and reset, the MM2S_THRESHOLD Register (Offset 0x1C) is set to this value.

Note: The maximum threshold value is limited by C_MM2S_LINEBUFFER_DEPTH

C_S2MM_LINEBUFFER_THRESH

- Type: Integer
- Allowed Values: 1 to 65536 (default = 4)
- Definition: S2MM line buffer almost full threshold in bytes
- **Description:** Almost Full Threshold. Sets the default threshold point at which the MM2S line buffer almost full flag asserts high. Threshold can be modified dynamically during run time by writing to the S2MM_THRESHOLD register. The threshold is specified in bytes and must be multiple of C_S_AXIS_S2MM_TDATA_WIDTH/8. If C_S_AXIS_S2MM_TDATA_WIDTH is a

C_S_AXIS_S2MM_IDATA_WIDTH/8. If C_S_AXIS_S2MM_IDATA_WIDTH is a non-power of 2, the line buffer threshold value should be calculated based on the nearest upper power of 2 value.

For example, if C_S_AXIS_S2MM_TDATA_WIDTH = 24, the threshold values should be calculated based on the nearest upper power of 2, that is, $C_S_AXIS_S2MM_TDATA_WIDTH = 32$.

The following table illustrates the stream data width and its corresponding allowed line buffer threshold values

Stream Data Width	Allowed Values
8	1, 2, 3,
16	2, 4, 6,
24, 32	4, 8, 12,
48, 64	8, 16, 24,
96, 128	16, 32, 48,
192, 256	32, 64, 96,
384, 512	64, 128, 192,
768, 1024	128, 256, 384,

On power up and reset, the S2MM_THRESHOLD Register (Offset 0x4C) is set to this value.

Note: The maximum threshold value is limited by C_S2MM_LINEBUFFER_DEPTH.

Core Implementation

Functional Simulation

VHDL and Verilog source files for axi_vdma_v5_00_a are provided un-encrypted for use in behavioral simulation within a simulation environment. Neither a test bench nor test fixture is provided with the AXI VDMA core.

Synthesis

Synthesis of the AXI VDMA can be performed with XST.

When using ISE® design suite Project Navigator, the Library for Verilog Sources for AXI VDMA needs to be set to axi_vdma_v5_00_a. This is done from the ISE design suite Project Navigator GUI on the Design tab by right-clicking on **Synthesize - XST**. Then select **Process Properties**... from the pop-up window. At the bottom of the dialog box, set the Property display level to 'Advanced' by selecting it from the drop-down menu. Finally under the Synthesis Options category, find the Property Name 'Library for Verilog Sources' and enter a value of axi_vdma_v5_00_a.

Xilinx Tools

See the LogiCORETM IP Facts table on page 4.

Static Timing Analysis

Static timing analysis can be performed using *trce*, following *ngdbuild*, *map*, and *par*.

www.xilinx.com

AXI VDMA Operation

Register Direct Mode Operation (C_INCLUDE_SG = 0)

For operations without a scatter gather engine, an expanded AXI4-Lite register map is provided, exposing the video specific register fields to read and write via the AXI4-Lite interface (See Figure 1-1 and Table 2-3). These registers include the DMACR, DMASR, PART_PTR_REG, VIDEO_VERSION, VSIZE, HSIZE, FRMDLY_STRIDE, REG_INDEX, and START ADDRESS/ES for each respective channel. Some applications for Register Direct mode include systems that do not have a CPU.

VDMA operations in register direct mode begin with the set up of the video parameter and start address registers and the DMA control registers. The following lists minimum steps, in order, required to start AXI VDMA operations:

- 1. Write control information to channel's DMACR register (Offset 0x00 for MM2S and 0x30 for S2MM) to set interrupt enables if desired, frame count, delay count if desired, and set DMACR.RS=1 to start the AXI VDMA channel running. There can be a lag between when the CPU sets DMACR.RS=1 and when AXI VDMA sets DMASR.Halted = 0. The CPU can determine if the AXI VDMA is running when DMACR.RS = 1 and DMASR.Halted = 0.
- 2. Write valid video frame buffer start address to the channel's START_ADDRESS register 1 to N where N equals C_NUM_FSTORES (Offset 058 up to 0x98 for MM2S and 0xAC up to 0xE8 for S2MM). Set the REG_INDEX register as and if required.
- 3. Write a valid Frame Delay and Stride to the channel's FRMDLY_STRIDE register (Offset 0x58 for MM2S and 0xA8 for S2MM).
- 4. Write a valid Horizontal Size to the channel's HSIZE register (Offset 0x54 for MM2S and 0xA4 for S2MM).
- 5. Finally write a valid Vertical Size to the channel's VSIZE register (Offset 0x50 for MM2S and 0xA0 for S2MM). This starts the channel transferring video data.

Note: On the S2MM channel, new video line size and number of video lines need to change following the assertion of $s_{2mm}prmtr_update$ or undefined results occur.

Updating Video Transfer Information

In Register Direct Mode (C_INCLUDE_SG = 0), the user should be able to update video parameter settings at any time while the engine is running by writing new video parameters and a video start address through the AXI4-Lite control interface. The newly written video transfer values take effect on the next frame boundary after the user writes the vertical size register for the respective channel. The channel's pmrtr_update output (mm2s_prmtr_update and s2mm_prmtr_update) for the respective channel asserts, indicating the new video parameters are being used by the AXI VDMA.

To update video parameters dynamically while AXI VDMA operations are ongoing, a similar process to the start steps is needed.

- 1. Write the Frame Delay, Stride, and Horizontal Size in any order for the associated channel.
- 2. Finally, write the Vertical Size. When VSize is written, the video register values are transferred to an internal register block. On the next frame boundary the DMA controller for the associated channel starts transfers using the newly updated values.

For applications where reading of the video parameters and start address registers is not needed, the FPGA resources can be reduced by excluding the read logic for the video specific registers (VSIZE, HSIZE, FRMDLY_STRIDE, and START ADDRESS/ES). This is accomplished by setting C_ENABLE_VIDPRMTR_READS = 0.

Scatter Gather Mode Operation (C_INCLUDE_SG = 1)

AXI VDMA operation requires a memory-resident data structure that holds the list of DMA operations to be performed. This list of instructions is organized into what is referred to as a descriptor chain. Each descriptor has a pointer to the next descriptor to be processed. The last descriptor in the chain then points back to the first descriptor in the chain.

VDMA operations began with the setup of the descriptor pointer registers and the DMA control registers. The following lists minimum steps, in order, required for AXI VDMA operations:

- 1. Write a valid pointer to the channel's CURDESC_PNTR register (Offset 0x08 for MM2S and 0x38 for S2MM).
- 2. Write control information to channel's DMACR register (Offset 0x00 for MM2S and 0x30 for S2MM) to set interrupt enables if desired, frame count, delay count if desired, and set DMACR.RS=1 to start the AXI VDMA channel running. There can be a lag between when the CPU sets DMACR.RS=1 and when AXI VDMA sets DMASR.Halted = 0. The CPU can determine if the AXI VDMA is running when DMACR.RS = 1 and DMASR.Halted = 0.
- 3. Write a valid point to the channel's TAILDESC_PNTR register (Offset 0x10 for MM2S and 0x40 for S2MM). This starts the channel fetching and processing descriptors.
- 4. DMA scatter gather operations continue until the descriptor at TAILDESC_PNTR is processed, and then the engine idles as indicated by DMASR.Idle = 1.

The descriptor chain is made up of a maximum of C_NUM_FSTORES descriptors per channel. The SG Engine fetches descriptors and updates an internal register set with the descriptor information. (See Figure 4-2.) The video timing information (vsize, hsize, stride, and frame delay) from the first descriptor fetched is captured and stored.

This video timing information is used for all transfers in all frames for the specified channel. All other video timing information in the other descriptors is ignored by the AXI VDMA. Start Addresses from each descriptor are populated into C_NUM_FSTORES internal address registers.

When the SG Engine reaches the descriptor pointed to by TAILDESC, the SG Engine processes that descriptor, sets the internal register set to ping-pong on the next frame sync (Internally generated if C_USE_FSYNC = 0 or externally if C_USE_FSYNC = 1), and enters an Idle state. At the next frame sync, the internal register set will switch such that the DMA controller operates on the newly updated values.

This method for handling data updates internally allows the SG engine to operate on a register set without stepping on the register set that the DMA controller is using for data transfers. It also allows the SG Engine to only fetch descriptors when a change is made to the data set, making it unnecessary for the SG engine to fetch a descriptor with each frame. The DMA controller continues to transfer video data even though the SG engine has reached the tail pointer and paused. This allows uninterrupted video data transfers.

Updating Video Transfer Information

To update the video transfer information for a channel, the CPU writes a new start address, vsize, hsize, stride, and frame delay information into the descriptor following the TAILDESC position. Then the CPU writes a new TAILDESC pointing to this newly updated descriptor. The SG Engine automatically fetches the newly updated descriptor and updates the start address, vsize, hsize, stride, and frame delay to the internal SG labeled register block. On the next frame sync for the channel these newly updated values are transferred to the Video labeled register block for use by the channel's DMA controller. The outputs, mm2s_prmtr_update and s2mm_prmtr_update, for the respective channel asserts coincident with mm2s_fsync and s2mm_fsync respectively when the new parameters take effect for the channel.

Note: On the S2MM channel, new video line size and number of video lines need to change following the assertion of $s2mm_prmtr_update$ or undefined results occur.

The entire descriptor chain can be updated in this manner, allowing a completely new set of start addresses and vsize, hsize, stride, and frame delay to be fetched and updated to the DMA controller. Update the descriptor chain and then write a TAILDESC pointer pointing to the last descriptor in the chain. All C_NUM_FSTORES descriptors are fetched.

The CPU should only update the TAILDESC when the engine is Idle; otherwise, undefined results occur. Updating the TAILDESC register when the SG Engine is Idle ensures that video timing information is not ignored in the descriptor.

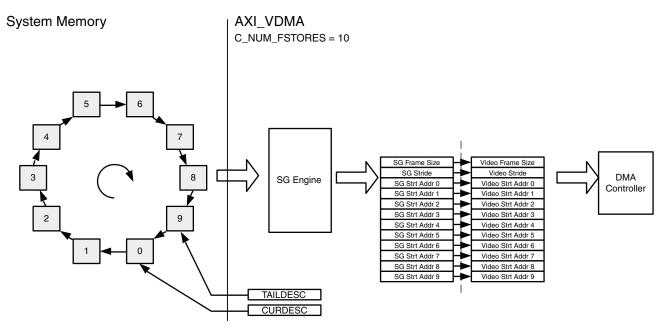

Figure 4-2: Example SG Fetch with C_NUM_FSTORES= 10

The AXI VDMA Scatter Gather engine has independent descriptor queues for fetch descriptors for the MM2S and S2MM channels. Independent register sets and DMA controllers for MM2S and S2MM are also provided.

Scatter Gather Descriptor

When the AXI VDMA is configured for Scatter Gather Mode (C_INCLUDE_SG = 1), the Scatter Gather engine is used to pull in video transfer control information. This is accomplished by defining a linked list of transfer control information referred to as a descriptor chain in system memory. A descriptor chain is required for each channel. The descriptor chain should be made up of MM2S_FRMSTORE and S2MM_FRMSTORE descriptors, respectively, where each descriptor is made up of seven 32-bit words. Each descriptor fields. For Register Direct Mode (C_INCLUDE_SG = 0) the Scatter Gather engine is excluded and the video parameter and start address registers are accessed through the AXI4-Lite Control Interface.

Note: Descriptors must be aligned on eight 32-bit word alignment. Example valid offsets are 0x00, 0x20, 0x40, 0x60, and so on.

Address Space Offset ^a	Name	Description
00h	NXTDESC	Next Descriptor Pointer points to the first word of the next descriptor to fetch.
04h	RESERVED	N/A
08h	START_ADDRESS	Start Address points to the starting pixel to transfer for the given frame.
0Ch	RESERVED	N/A
10h	VSIZE	Vertical Size specifies the number of video lines to transfer for the given frame.
14h	HSIZE	Horizontal Size specifies the size in bytes of the horizontal line to transfer for a given frame.
18h	FRMDLY_STRIDE	Stride specifies the number of bytes between the first pixels of each horizontal line.
1011	TRIVIDLI_51RIDE	Frame Delay specifies the number of frames a Genlock slave should be behind the Genlock Master.

Table 4-5: Descriptor Fields

a. Address Space Offset is relative to eight 32-bit word alignment in system memory, that is, 0x00, 0x20, 0x40 and so on.

NXTDESC (Next Descriptor Pointer)

This value provides the pointer to the next descriptor in the descriptor chain.

Г	31 NXTDESC Pntr 5		4	3	2	1	0
L		Ľ	4	2	Z	i	0

Rsvd

Table 4-6:	Ν	XTDESC Detai	ls
1			

Bits	Field Name	Description
31 downto 5	Next Descriptor Pointer	Indicates the lower order pointer pointing to the first word of the next descriptor. Note: Descriptors must be 8-word aligned, that is, 0x00, 0x20, 0x40, and so on. Any other alignment has undefined results.
4 downto 0	Reserved	These bits are reserved and should be set to zero.

START_ADDRESS (Start Address)

This value provides the pointer to the buffer of data to transfer from system memory to stream.

31	Start Address	0

Figure 4-4: Start Address

Table 4-7: START_ADDRESS Details

Bits	Field Name	Description
		Provides the starting pixel location of the data to transfer. For MM2S channel, data is read from system memory starting at this address. For S2MM channel, data is written to system memory starting at this address.
31 downto 0	Start Address	Note: If the Data Realignment Engine is included (C_INCLUDE_MM2S_DRE = 1 or C_INCLUDE_S2MM_DRE = 1) for the respective channel, the Start Address can be at any byte offset. If the Data Realignment Engine is not included (C_INCLUDE_MM2S_DRE = 0 or C_INCLUDE_S2MM_DRE = 0) for the respective channel, the Start Address must be stream data width aligned.

VSIZE (Vertical Size)

This value provides vertical size (or number of lines) to transfer.

31 Reserved	3 12	Vsize (Lines)	0
-------------	------	---------------	---

Figure 4-5: VSIZE

Bits	Field Name	Description
31 downto 13	Reserved	This bit is reserved and should be written as zero.
12 downto 0	VSize	Vertical size in lines of the video data to transfer. On the MM2S stream interface there are vsize number of packets that are hsize bytes long transmitted for each frame. On the S2MM stream interface, the vsize number of packets that are hsize bytes long are expected to be received for each frame.
		<i>Note:</i> A value of zero on Vsize causes a MM2S_DMAIntErr or S2MM_DMAIntErr for the associated channel to be logged and the channel with the detected error is shut down.

Table 4-8: VSIZE Details

HSIZE (Horizontal Size)

This value provides horizontal size in bytes of the video line to transfer.

31 Reserved 16 15 Hsize (Bytes) 0

Figure 4-6: HSIZE

Table 4-9: HSIZE Details

Bits	Field Name	Description
31 downto 16	Reserved	These bits are reserved and should be set to zero.
15 downto 0		Horizontal size in bytes of the video data to transfer. On the MM2S stream interface there are vsize number of packets that are hsize bytes long transmitted for each frame. On the S2MM stream interface, vsize number of packets that are hsize bytes long are expected to be received for each frame.
	HSize	<i>Note:</i> If more or less data are received on the S2MM stream interface, an underrun or overrun error occurs. This presents itself as a S2MM_DMASR.DMAIntErr and the AXI VDMA S2MM channel is shut down.
		<i>Note:</i> A value of zero for Hsize causes a MM2S_DMAIntErr or S2MM_DMAIntErr for the associated channel to be logged and the channel with the detected error is shut down.

FRMDLY_STRIDE (Frame Delay and Stride)

This value provides the Genlock Frame Delay and Stride for the video transfer.

Figure 4-7: FRMDLY_STRIDE

Bits	Field Name	Description
31 downto 29	Reserved	These bits are reserved and should be set to zero.
28 downto 24	FrmDly	Frame Delay is the number of frame stores that the slave should be behind the locked master. This field is only used if the channel is enabled for Genlock Slave Operations (C_MM2S_GENLOCK_MODE = 1 or C_S2MM_GENLOCK_MODE=1) for the respective channel. Note: Frame Delay must be less than or equal to MM2S_FRMSTORE or S2MM_FRMSTORE for the respective channel or undefined results occur.
23 downto 16	Reserved	These bits are reserved and should be set to zero.
15 downto 0	Stride	Number of bytes between first pixels of each video line. <i>Note:</i> Stride values less than HSize results in corrupt data.

Table 4-10: FRMDLY_STRIDE Details

AXI VDMA General Operations

AXI VDMA Frame Boundary

A frame boundary depends on the mode of operation. For external fsync mode (C_USE_FSYNC = 1) the frame boundary is based on the channel's fsync input, mm2s_fsync or s2mm_fsync. AXI VDMA starts the transfer for a particular frame after driving out an fsync_out for the associated channel (mm2s_fsync_out or s2mm_fsync_out). There is some pipeline delay between the fsync input and when fsync_out is driven.

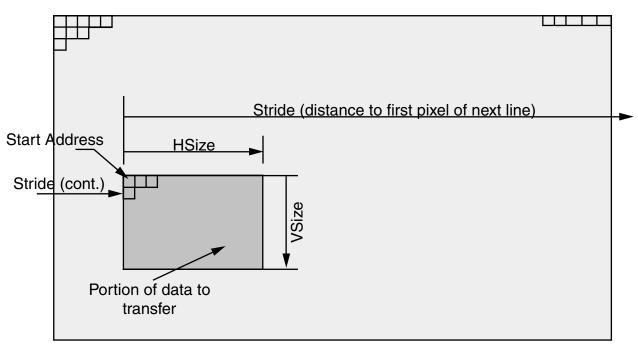

For free run mode (C_USE_FSYNC = 0) an internal fsync is generated for timing transfers. AXI VDMA transfers the commanded transfers as quickly as it is able to process and transfer the data. AXI VDMA will drive out an fsync_out for the associated channel, mm2s_fsync_out or s2mm_fsync_out, on each frame boundary.

In both free run and external fsync modes on S2MM, AXI VDMA asserts <code>s_axis_s2mm_tready</code> after <code>s2mm_fsync_out</code> asserts, indicating to the attached video IP that AXI VDMA is ready to accept data. At the end of each frame, when all expected data are received, the AXI VDMA deasserts <code>s_axis_s2mm_tready</code> until the start of the next frame as indicated by the assertion of <code>s2mm_fsync_out</code>.

When new video parameters have been updated to AXIVDMA and the associated channel starts operating on the new video parameters and start addresses, AXIVDMA asserts the associated channel prmtr_update, mm2s_prmtr_update or s2mm_prmtr_update, coincident with fsync_out for the associated channel. This indicates to the attached video IP that new line length and/or line number is in effect.

AXI VDMA Video Transfer

Data is transferred from System Memory to Stream or Stream to System Memory as defined by the Start Address for the frame currently being operated on and the vertical size, horizontal size, and stride. Figure 4-8 illustrates a typical video image stored in system memory. The smaller portion of the video image is to be transferred. Vertical Size lines of Horizontal Size number of bytes are transferred from or to system memory starting at each start address for each video frame.

Frame of Image Data

X12150

Figure 4-8: Example Video Image Transfer

Free Run Mode (C_USE_FSYNC = 0)

In free run mode (C_USE_FSYNC = 0), video data are transferred as quickly as possible. The output ports mm2s_fsync_out and s2mm_fsync_out indicate the frame boundaries. On start-up, that is, DMACR.RS set to 1 for the respective channel, an initial frame sync (mm2s_fsync_out or s2mm_fsync_out) asserts after the video parameters have been updated. This initial assertion of frame sync indicates the beginning of the first frame. For the MM2S channel, video data for a frame is transferred after the assertion of each mm2s_fsync_out. For the S2MM channel, axi_vdma expects new data for the frame to be transferred to the s2mm channel after the assertion of s2mm_fsync_out.

The AXI4-Stream output port, s_axis_s2mm_tready, asserts after s2mm_fsync_out, indicating the S2MM channel is ready to receive data. When all expected data (vsize lines that are hsize bytes long) have been received, AXI VDMA deasserts

s_axis_s2mm_tready and does not reassert until the next s2mm_fsync_out. For both channels, MM2S and S2MM, when configured for free run mode, mm2s_fsync_out and s2mm_fsync_out asserts only after all of the data for a frame have been transferred. In free run mode the progression of video frames is in part controlled by the target Video IP on the MM2S or S2MM AXI4-Stream. For MM2S, if m_axis_mm2s_tready is not asserted, then the frame time for mm2s is extended. Only after all video lines have been transferred is the frame considered complete and a new mm2s_fsync_out asserts. Likewise, on S2MM, if s_axis_s2mm_tvalid is not asserted, the frame time for s2mm is extended. Only after all video lines have been transferred is the frame considered complete and a new s2mm_fsync_out asserted.

Frame Sync Mode (C_USE_FSYNC = 1)

In frame sync mode, video data is synchronized to an external frame sync, mm2s_fsync for the MM2S channel and s2mm_fsync for the S2MM channel. The axi_vdma channel begins each frame on the falling edge of the associated channel's frame sync input, mm2s_fsync or s2mm_fsync. For the MM2S channel, data is driven out on the Master AXI4-Stream port following the assertion of mm2s_fsync. It is the responsibility of the target video IP to accept all transferred video lines before the assertion of the next mm2s_fsync or undefined results occur. For the S2MM channel, data is accepted on the Slave AXI4-Stream port following the assertion of s2mm_fsync. Again, the S2MM AXI4-Stream output port s_axis_s2mm_tready asserts after s2mm_fsync_out indicating that the S2MM channel is ready to receive data for a particular video frame, and deasserts s_axis_s2mm_tready when all expected data for the frame has been received.

It is the responsibility of the target video IP to transfer all video lines before the assertion of the next s2mm_fsync or undefined results occur.

The minimum time between assertions of the associated channel's fsync input, $mm2s_fsync$ or $s2mm_fsync$, has been verified via simulation down to 1 µsec. Fsync rates faster than 1 µsec between assertions produce undefined results.

Figure 4-9 illustrates three frames worth of image transfer. MM2S channel reads from Frame 0 then on MM2S Frame Sync transitions to reading from Frame 1. Then Frame 2, and back to Frame 0 continuing this cycle with each Frame sync. S2MM writes to Frame 1 then transitions to Frame 2, followed by Frame 0. S2MM continues this progressing with each S2MM Frame Sync. To keep S2MM and MM2S from stepping on each other Genlock synchronization is used.

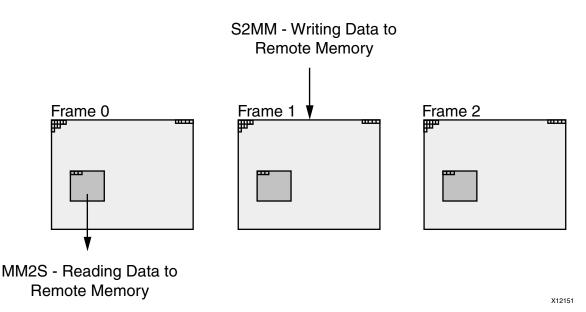

Figure 4-9: Three Frame Example with S2MM and MM2S

Genlock Synchronization

In many video applications, a producer of data runs at a different rate than the consumer of that data. To avoid the potential ill effects that such a rate mismatch can cause, frame buffering is often used. Frame buffering allocates multiple frames worth of memory to be used to hold the data. The data producer writes to one buffer while the consumer reads from another. See Figure 4-9. The two are kept in sync by not allowing both to use the same buffer at the same time. Typically one of the two is forced to either skip or repeat frames as necessary. This type of synchronization is called Genlock and is provided when the axi_vdma is configured for frame sync mode (C_USE_FSYNC = 1). Each channel of AXI VDMA has been designed to operate as either a Genlock Master or Slave. In general, a Genlock master specifies to a Genlock slave which frame to operate on at any given time.

Figure 4-10 illustrates simple timing of Genlock operation. In this example MM2S_FRMSTORE = 3, S2MM_FRMSTORE = 3, C_USE_FSYNC = 1, the frame delay for S2MM has been set to 1. Also, MM2S has been configured as the Genlock Master and S2MM channel has been configured as the Genlock Slave. The MM2S channel's frame rate is faster than that of S2MM so the S2MM Slave skips frames automatically. As one can see in Figure 4-10, in the time the MM2S channel cycles through frame 0, 1, 2 and back to 0, the S2MM channel has only cycled through two frame. Due to the slow frame rate of S2MM compared to MM2S, the S2MM channel processes frame 2 then frame 0 then frame 2 again, skipping frame 1.

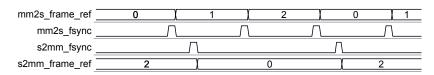

Figure 4-10: Example Genlock Timing

The Genlock mechanism that the AXI VDMA implements is based around the internal Start Address registers. The number of Start Address registers can be configured to be between 1 and 16. MM2S_FRMSTORE and S2MM_FRMSTORE specify this value for the associated channel with the C_NUM_FSTORES parameter specifying the maximum value. If large numbers of Frame Stores are not required, then specifying smaller values of C_NUM_FSTORE saves FPGA resources. The Genlock Master uses the index of the Start Address register to specify which Start Address register the Genlock Slave should use. This Start Address Register index is encoded as a Grey code value. The Grey Code that is used depends upon the number of Frame Stores that was specified. Table 4-11 lists the Grey Codes that are used for each of the 16 possible Frame Store sizes. The Grey Code cycles through all of the codes on the first line first and then cycles through all of the codes on the second line before repeating the first line. Number of grey codes is double the number of frame stores to allow for non-power-of-two frame store values to be cycled through and still maintain grey code coherency with minimal FPGA resources required.

Table 4-11:	Genlock G	rey Code
-------------	-----------	----------

FRMSTORE			Grey Code

Table 4-11: Genlock Grey Code (Cont'd)

The grey codes received by the Genlock slave are then converted to a frame reference to tell the Genlock slave which frame to work on. The slave modifies the Genlock frame reference received by the frame delay such that the Genlock slaves remain a Frame Delay behind the Genlock Master. Table 4-12 illustrates an example conversion from Genlock Grey Code to Frame Reference used by the Genlock Slave.

Grey To Frame Conversion	Grey Code Progressions for NUMFSTORE = 5									
Grey Code	2	6	7	5	4	12	13	15	14	10
Decoded Frame Reference	0	1	2	3	4	0	1	2	3	4

Table 4-12: Example Grey Code Conversion for NUMFSTORE = 5

Line Buffers

An optional line buffer can be utilized to prevent memory controller throttling from causing inner packet throttling on the stream interface. The user can configure line buffer depth (via C_MM2S_LINEBUFFER_DEPTH and C_S2MM_LINEBUFFER_DEPTH) to provide the necessary buffering for a specific video application. For transmit (MM2S), this line buffering presents several clocks of latency at the onset of a video frame transfer between system memory read and initial tvalid on AXI4-Stream as the line buffer queues up a portion of the data to transfer.

Line buffer status is provided for video IP use. The signals mm2s_linebuffer_empty and mm2s_linebuffer_almost_empty are provided for the MM2S channel and s2mm_linebuffer_full and s2mm_linebuffer_almost_full are provided for the S2MM channel. Threshold parameters are provided to specify the assertion points for mm2s_linebuffer_almost_empty and s2mm_linebuffer_almost_full.

Note: Due to pipelining in the fifo_generated FIFOs and also clock crossing of asynchronous FIFOs, s2mm_linebuffer_almost_full and mm2s_linebuffer_almost_empty CANNOT be cycle accurate, meaning, for example, if the threshold is set to 8 bytes then mm2s_linebuffer_almost_empty does not deassert on the next clock cycle after the 8th byte is written into the FIFO. The almost_empty flag deasserts several (pipeline depth and possible clock crossing logic depth) cycles later.

Dynamic Line Buffer Threshold

For MM2S, the MM2S_THRESHOLD register (Offset 0x1C) specifies the assertion point for mm2s_buffer_almost_empty. The default value for this register is set via the C_MM2S_LINEBUFFER_THRESH parameter. The threshold register value is specified in bytes and must be a power of two value, that is, 1, 2, 4, 8, and so on. C_MM2S_LINEBUFFER_THRESH specifies the assertion point for mm2s_buffer_almost_empty. The mm2s_buffer_almost_empty signal asserts when there are MM2S_THRESHOLD bytes or less left in the Line Buffer. For example, if MM2S_THRESHOLD = 8 then mm2s_buffer_almost_empty asserts when the number of stored bytes is 8, 7, 6, 5, 4, 3, 2, or 1. When byte count = 0 then mm2s_buffer_almost_empty remains asserted and mm2s_buffer_empty will assert.

To prevent throttling within a MM2S AXI4-Stream packet, the target Video IP is responsible for not asserting $m_axis_mm2s_tready = 1$ until $mm2s_buffer_almost_empty$ deasserts and $mm2s_buffer_empty = 0$, indicating more than MM2S_THRESHOLD data are stored in the line buffer. Adjustments might need to be made to the MM2S_THRESHOLD value for a user application to prevent throttling within packets.

For S2MM, the S2MM_THRESHOLD register (Offset 0x4C) specifies the assertion point for s2mm_buffer_almost_full. The default value for this register is set via the C_S2MM_LINEBUFFER_THRESH parameter. This allows for backwards compatibility with previous versions of AXI VDMA. The threshold register value is specified in bytes and must be a power of 2 value, that is, 1, 2, 4, 8, and so on. S2MM_THRESHOLD specifies the assertion point of s2mm_buffer_almost_full. s2mm_buffer_almost_full asserts when there are S2MM_THRESHOLD bytes or more in the Line Buffer. For example, if S2MM_THRESHOLD = 8 then s2mm_buffer_almost_full asserts when the number of stored bytes is 8 or greater. When line buffer is full then both s2mm_buffer_almost_full and s2mm_buffer_full asserts. s2mm_buffer_full asserts when the last data beat of space is occupied. A data beat of space is C_S_AXIS_S2MM_TDATA_WIDTH bits wide.

Store-And-Forward

For cases where the target IP may throttle back on AXI VDMA, optional Store-And-Forward can be utilized. When included, a Store-And-Forward buffer and manager are instantiated in AXI VDMA. On MM2S, this prevents the channel from requesting more read data than can be held in the Store-And-Forward buffer. On S2MM this prevents the channel from issuing write requests when there is not enough data in the Store-And-Forward buffer to complete the write. For MM2S and S2MM, if the AXI4 data width equals the AXI4 Stream data width, that is, C_M_AXI_MM2S_DATA_WIDTH = C_M_AXIS_S2MM_TDATA_WIDTH and

 $C_M_AXI_S2MM_DATA_WIDTH = C_S_AXIS_S2MM_TDATA_WIDTH$, and Store-And-Forward is included, AXI VDMA does not throttle back on the AXI4 Slave for reads or writes. For cases when the data widths do not match, the data has to be unpacked for MM2S and packed for S2MM, causing brief periodic throttles during the burst.

Additionally if Store-And-Forward is included and the Line Buffer for the associated channel is included, then both features share a common buffer the depth of which is determined by the maximum of the Line Buffer Depth setting and what is required for Store-And-Forward.

On MM2S, when Store-And-Forward and the Line Buffer are enabled, then the AXI4-Stream data valid (m_axis_mm2s_tvalid) does not assert until an initial threshold, C_MM2S_LINEBUFFER_THRESH, is met. This allows the target IP to ignore the side band mm2s_buffer_almost_empty flag and rely on the assertion of m_axis_mm2s_tvalid to determine when enough MM2S data has been queued.

Example MM2S Timing

Figure 4-11 illustrates example timing on MM2S channel for C_USE_FSYNC = 1, Vertical Size = 5 lines, Horizontal Size = 16, bytes, and Stride = 32 bytes. The figure shows the m_axi_mm2s and m_axis_mm2s interfaces.

Dataflow: After the reception of mm2s_fsync, AXI VDMA asserts

m_axi_mm2s_arvalid with the start address on m_axi_mm2s_araddr. The signal m_axi_mm2s_arvalid is asserted five times to fetch five (vsize) lines of a frame. Read data from the mm side is stored in the line buffer and delivered on the streaming side by asserting m_axis_mm2s_tvalid. The signal m_axis_mm2s_tlast is asserted at the end of each line.

Figure 4-12: Example S2MM Interface Timing

Example Scatter Gather Timing

Figure 4-13 illustrates example timing for the Scatter Gather interface. The figure shows m_axi_sg interface timing with respect to m_axi_mm2s interface.

Dataflow: The SG engine starts when TAILDESC POINTER is written with a new value. C_NUM_FSTORES is programmed to 3. A chain of three descriptors are fetched. The signal mm2s_fsync is not sampled until AXI VDMA has completed fetching C_NUM_FSTORES of descriptors. On completion of descriptor fetching, AXI VDMA drives mm2s_fsync_out to signal a new frame start boundary. AXI VDMA then asserts m_axi_mm2s_arvalid with the start address on m_axi_mm2s_araddr. The signal m_axi_mm2s_arvalid is asserted five times to fetch five (vsize) lines of a frame. Read data from the mm side is stored in the line buffer and delivered on the streaming side by asserting m_axis_mm2s_tvalid. The signal m_axis_mm2s_tlast is asserted at the end of each line.

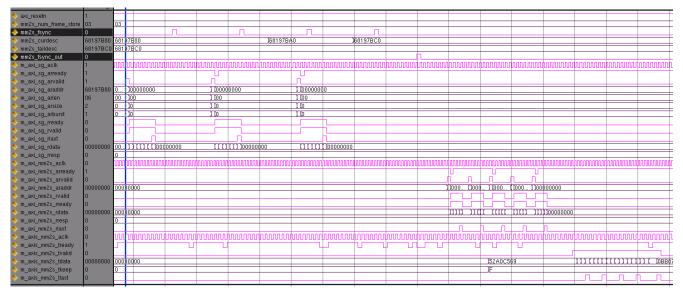

Figure 4-13: Example Scatter Gather Timing

AXI VDMA System Configuration

System configuration should be taken into consideration when using AXI VDMA. Due to the high performance and low latency design of AXI VDMA throttling or back pressure on the AXI4-Stream ports of AXI VDMA (MM2S and S2MM), this subsequently applies back pressure on the associated channel's AXI4 Memory Map side.

Depending on a user's system configuration, this back pressure can lead to a deadlock situation where, for example, a write transfer on S2MM to a single ported memory controller cannot complete because of a throttled read transfer on MM2S. A loopback type system where MM2S stream interface is looped back to S2MM stream interface can present such a deadlock scenario.

Two methods for resolving this deadlock scenario are provided, enabling the AXI Interconnect's FIFO blocks or including the Store-And-Forward feature on AXI VDMA.

AXI Interconnect Solution

The AXI Interconnect interfacing to the AXI VDMA AXI4 Memory Map ports on MM2S and S2MM can be configured to prevent the deadlock scenario described in the preceding paragraph. Read and Write Data FIFOs can be turned on in the AXI Interconnect to allow read and/or write data to be buffered up. Enabling the FIFOs along with limiting the number of outstanding read and write requests accepted by AXI Interconnect guarantees that all requested data to be transferred can be accepted by the AXI Interconnect preventing deadlock.

To enable these AXI Interconnect features, four non-HDL parameters are provided:

- C_INTERCONNECT_M_AXI_MM2S_READ_ISSUING
- C_INTERCONNECT_M_AXI_MM2S_READ_FIFO_DEPTH
- C_INTERCONNECT_M_AXI_S2MM_WRITE_ISSUING
- C_INTERCONNECT_M_AXI_S2MM_WRITE_FIFO_DEPTH

Setting these parameters correctly configures the AXI Interconnect interfaced to the Memory Map ports of the AXI VDMA. For AXI VDMA, *_ISSUING multiplied by the associated channels *_MAX_BURST_LENGTH must be less than the *_FIFO_DEPTH to prevent a the deadlock scenario. For example, if C_MM2S_MAX_BURST_LENGTH is set to 16 and C_INTERCONNECT_M_AXI_MM2S_READ_ISSUING is set to 4, then the product of these two values is 16 X 4 = 64. Therefore, the setting C_INTERCONNECT_M_AXI_MM2S_READ_FIFO_DEPTH = 512 is sufficient to satisfy the requirements (16 X 4 = 64 which is less than 512). Following is the formula presented for clarity:

*_MAX_BURST_LENGTH X *_ISSUING < *_FIFO_DEPTH

When looking at FPGA resource utilization in an EDK system with AXI VDMA, the user should note that the AXI Interconnect instantiates FIFOs for both MM2S and S2MM channels of AXI VDMA.

Store-And-Forward Solution

With this latest revision of AXI VDMA, an optional store and forward feature has been added. This is the recommended solution to the deadlock scenario described previously. To enable this feature, set C_INCLUDE_MM2S_SF = 1 and C_INCLUDE_S2MM_SF = 1.

Interrupt Controller

An interrupt output is provided for each channel (MM2S and S2MM). This output drives High when the interrupt frame count is met, if there is a delay interrupt, or an error if the associated interrupt is enabled, as shown in Figure 4-14.

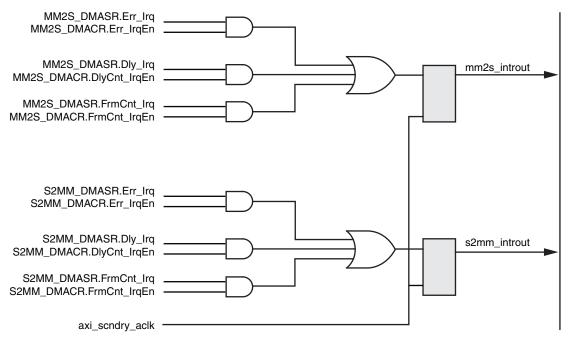

Figure 4-14: Interrupt Out Concept

Threshold Interrupt

Interrupt coalescing can be accomplished by setting the DMACR.IRQFrameCount field. With each frame completion event (that is, transmitted last line of frame or Received last line of frame when C_USE_FSYNC = 0 or on mm2s_fsync or s2mm_fsync for when C_USE_FSYNC = 1) the frame count is decremented. When the count reaches zero, FrmCnt_Irq asserts and if FrmCnt_IrqEn = 1, then an interrupt is generated on the associated channels introut signal (that is, mm2s_introut or s2mm_introut). When a frame count interrupt is generated, the frame count is reloaded in the counter in preparation for the next frame count event. The internal frame count value is presented to software in DMASR.IRQFrameCntSts. A DMACR.IRQFrameCount value of 0x01 (default) cause a single frame count interrupt event to immediately generate an interrupt out.

If the delay interrupt is enabled (DMACR.IRQDelayCount not equal to 0 and DMACR.DlyIrq_En = 1), then a delay interrupt event also reloads the internal frame count counter. Finally with each software write of the frame count value (DMACR.IRQFrameCount), the internal counter is reloaded.

Figure 4-15 illustrates the functional composition of the interrupt threshold logic.

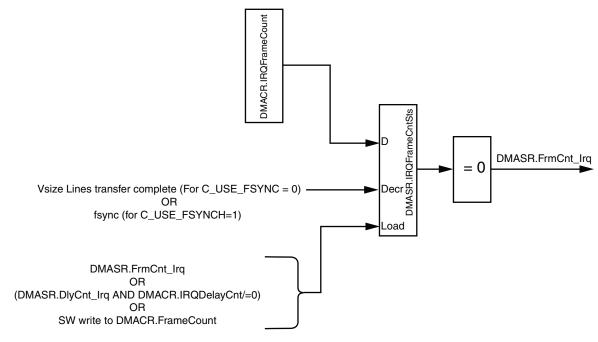

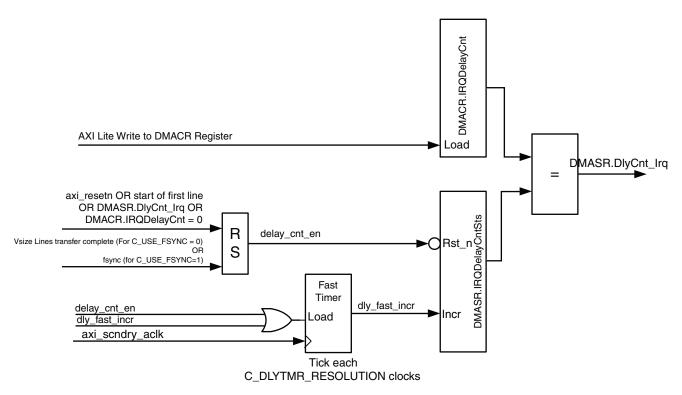

Figure 4-15: Frame Count Interrupt Logic Concept

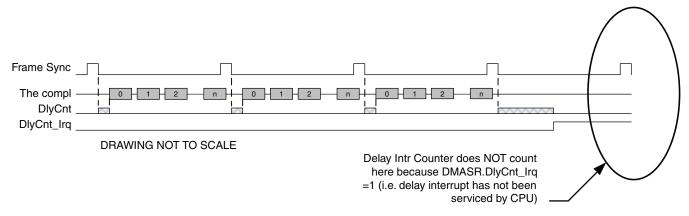

Delay Interrupt

The delay interrupt is a mechanism by which software can receive an interrupt even when the frame count is not met. This is useful primarily for the S2MM (receive) channel for when receive data are sporadic. The software can still get an interrupt and service what data are received even if the frame count has not been decremented to zero. Figure 4-16 shows a high-level block diagram of the delay interrupt architecture.

The delay count interrupt is enabled by setting the DMACR.IRQDelay value to a non-zero value. The delay counter begins counting up either upon receipt of frame sync (mm2s_fsync or s2mm_fsync) for C_USE_FSYNC = 1 or the completion of the transfer of vsize lines for the respective channel. The delay counter resets with each subsequent fsync or frame transfer completion. When a delay interrupt event occurs, the delay timer is reset to zero, generating a IRQDelayCount event. If the DMACR.DlyCnt_IrqEn = 1 for the respective channel, then an interrupt out is generated from AXI VDMA. The delay timer does not count until the CPU services the interrupt by clearing the DMASR.DlyCnt_Irq bit to 0. Figure 4-17 shows example timing for this situation.

www.xilinx.com

Errors

Any detected error on the primary datapath (that is, DMAIntErr, DMASlvErr, and DMADecErr) results in the associated channel (MM2S or S2MM) to halt gracefully when C_FLUSH_ON_FSYNC=0. Any Scatter Gather Engine detected error (that is, SGSlvErr or SGDecErr) causes the entire AXI VDMA engine to halt gracefully.

When an error is detected, the errored channel's DMACR.RS bit is set to 0. Per AXI protocol all AXI transfers on memory map interfaces must complete; therefore, the AXI VDMA completes all pending transactions (transactions already posted and accepted on memory map interfaces) before setting the errored channel's DMASR.Halted bit. When the DMASR.Halted bit is set to 1, then the AXI VDMA channel is truly halted.

Furthermore for DMA detected errors the associated channel's FrmStore pointer (RdFrmStore or WrFrmStore) is updated with the frame reference of the errored frame. For SG detected errors the descriptor associated with the errored transfer is updated to the channel's CURDESC pointer register. If multiple, simultaneous errors are detected, then only one of the detected error's CURDESC is updated.

To resume operations, a reset must be issued, either soft or hard. If using soft reset, then for Scatter gather errors a reset must be issued to both channels. For primary DMA errors, the reset must be issued only to the channel that logged the error. Hard resets, reset the entire AXI VDMA engine.

Here is a list of possible errors:

DMAIntErr (C_INCLUDE_SG = 1/0)

DMA Internal Error flags an internal error in the AXI DataMover was detected. This can occur under two conditions.

First, for MM2S and S2MM channels, it can occur when a BTT = 0 is written to the primary AXI DataMover. For Scatter Gather Mode (C_INCLUDE_SG = 1) this happens if a descriptor is fetched with the VSIZE or HSIZE = 0. For Register Direct Mode (C_INCLUDE_SG = 0) this happens if the VSIZE and/or HSIZE register for the respective channel = 0 when the VSIZE register was written.

Secondly, for S2MM channels, the internal error can occur if an underflow or overflow condition occurs on the S2MM primary stream interface.

An underflow is defined as a condition where a received packet contains less bytes than what is specified by the hsize field.

An overflow is defined as a condition where a received packet contains more bytes than what is specified by the hsize field.

DMASIvErr (C_INCLUDE_SG = 1/0)

DMA Slave Error occurs when the slave to/from which data are transferred responds with a SLVERR on the memory map interface.

DMADecErr (C_INCLUDE_SG = 1/0)

DMA Decode Error occurs when the address request is targeted to an address that does not exist.

SGSIvErr (C_INCLUDE_SG = 1)

Scatter Gather Slave Error occurs when the slave from which descriptors are fetched responds with a SLVERR.

SGDecErr (C_INCLUDE_SG = 1)

Scatter Gather Decode Error occurs when the address request is targeted to an address that does not exist.

Flush on Frame Sync

Flush on frame sync allows an AXI VDMA to reset internal states and flush transfer data on frame sync for certain error conditions. This allows VDMA to restart transfers at the beginning of a new frame after DMA Internal error detection instead of halting the channel. The AXI VDMA continues the operation for the following DMA internal error conditions when C_FLUSH_ON_FSYNC=1:

MM2S Channel

- Frame size Mismatch
 - The number of lines transmitted are more than the lines expected. VDMA is configured for Too Many Lines, that is, transmit more lines than expected in a frame. DMA internal error is flagged by VDMA and MM2S channel does not halt.
 - The number of lines transmitted are less than the lines expected. VDMA is configured for Too Few Lines, that is, transmit less lines than expected in a frame. DMA internal error is not flagged by VDMA as m_axis_mm2s_tvalid deasserts at the completion of requested lines and MM2S channel does not halt.

S2MM Channel

- Frame size Mismatch
 - The number of lines received are more than the lines expected. VDMA is configured for Too Many Lines, that is, receive more lines than expected in a frame. DMA internal error is flagged by VDMA and S2MM channel does not halt.
 - The number of lines received are less than the lines expected. VDMA is configured for Too Few Lines, that is, receive less lines than expected in a frame. DMA internal error is not flagged by VDMA as a_axis_s2mm_tready deasserts at the completion of requested lines and S2MM channel does not halt.
- Line size Mismatch
 - The number of bytes per line received are more than the bytes expected. VDMA is configured for Too Many Bytes, that is, receive more bytes than expected in a line. DMA internal error is not flagged by VDMA and S2MM channel does not halt.
 - The number of bytes per line received are less than the bytes expected. VDMA is configured for Too Few Bytes, that is, receive less bytes than expected in a line. DMA internal error is not flagged by VDMA and S2MM channel does not halt.

AXI VDMA MM2S/S2MM channels halts for the following error conditions even if C_FLUSH_ON_FSYNC = 1:

- DMA Internal error caused by setting VSIZE=0/HSIZE=0
- DMA/SG Decode Error
- DMA/SG Slave Error

Frame Advancement on Error

When an error is detected in a particular frame, this optional feature allows the user to let the frame number advance on the next frame sync or not advance and reuse the errored frame's frame number. This feature is only valid if C_MM2S_GENLOCK_MODE = 0, C_USE_FSYNC = 1, and C_FLUSH_ON_FSYNC = 1.

Error Priority

Table 4-13 shows the error priorities and when the errors might occur.

Table 4-13: Error Priority

Priority (1= highest priority)	Error	Occurrence					
1	Fetch SGSlvErr	Cannot occur simultaneous with Fetch SGDecErr.					
1	Fetch SGDecErr	Cannot occur simultaneous with Fetch SGSlvErr.					
2	DMAIntErr (that is, zero vsize or hsize error)	Cannot occur simultaneous with DMASlvErr or DMADecErr for the descriptor with the zero vsize or hsize error. Cannot occur simultaneously with Fetch SGDecErr, Fetch SGSlvErr, or Fetch SGIntErr for the descriptor with the zero vsize or hsize error. Can occur simultaneously with errors detected for other descriptors not having zero vsize or hsize error.					
3	DMAIntErr (that is, Overflow/Underflow)	Cannot occur simultaneous with zero vsize or hsize error. Cannot occur simultaneously with Fetch SGDecErr, Fetch SGSlvErr, for the descriptor associated with overflow or underflow. Can occur simultaneous with DMASlvErr or DMADecErr.					
3	DMADecErr	Cannot occur simultaneous with DMASlvErr.					
3	DMASlvErr	Cannot occur simultaneous with DMADecErr.					

Triple Frame Buffer Example

Triple buffers or drop/add frame synchronizers are a common use for the AXI VDMA. Triple buffers can be used to pass image frames between two distinct clock domains without shear. Shear occurs when a frame is read from memory but that frame is made up of two different write frames. When the read and write clocks are asynchronous, the read and write memory pointers will cross each other at some point in time resulting in shear. To avoid shear, read and write pointers are not allowed to cross each other which results in frames being repeated or skipped. One or more AXI VDMAs can be used to implement this feature.

Generic triple buffers get the name by using three distinct frame stores to write and read data into and from memory. At no time is the read or write frame location allowed to overlap the other (for example, one cannot read and write from frame store #1 at the same time). This removes the possibility of shear in the read image that is possible in a double buffer scheme. Generic triple buffers use the following rules to ensure that reads and writes do not occur in the same frame store.

- Because there are three distinct frame stores and two possible operations (read and write), one frame store is always available and is denoted as the extra frame.
- When the write frame finishes, its next frame location is the extra frame location. The extra frame's location becomes the write frame's location. In essence, the locations swap between write and extra when the write completes. If the swap occurs twice prior to read frame completion, a skip (drop) frame occurs.
- When the read frame finishes, its next frame location is the newer (more recently written) of the extra frame or read frame. If the read frame is newer than the extra frame, a repeat (add) frame occurs.

The AXI VDMA mimics triple buffer capabilities by using Genlock synchronization. See Genlock Synchronization. Genlock mode is different than the generic triple buffer. In a generic triple buffer, the write frame must know the extra frame location(s) and read frame location. Genlock mode removes this restriction by implementing an N buffer with N distinct frame stores. N is an integer value greater than the maximum ratio of (readClock/writeClock) or (writeClock/readClock). For example, reading at a clock rate of 74.25 MHz and writing at a clock rate of 148.5 MHz gives a maximum ratio of 2 and requires N=3 distinct frame stores (C_NUM_FSTORES = 3). Reading at a clock rate of 148.5 MHz and writing at a clock rate of 74.25 MHz gives the same maximum ratio of 2 with the same requirement of N=3. Generic triple buffers work by reading the last full frame written. Genlock mode enhances this capability by allowing the user to read an arbitrary number of frames behind the write frame by only modifying the FRMDLY register. This can be extremely useful in applications such as deinterlacing or motion adaptive noise reduction.

The following sequence details the steps required to implement a triple buffer with the AXI VDMA.

- 1. Configure the core with the following parameters.
 - a. Determine the value to use for Frame Stores. This integer value should be greater than the maximum ratio of read and write clocks.
 - b. Enable
 - i. Use Frame Sync
 - ii. Asynchronous Clocks
 - iii. Flush on Frame Sync
 - iv. MM2S and S2MM Channel
 - v. MM2S and S2MM Store and Forward
 - vi. S2MM Frame Advancement on Error
 - c. Disable
 - i. Scatter Gather Engine.
 - d. Set S2MM Genlock Mode to Slave.
 - e. Per user requirements
 - i. Set stream data widths to user data sizes.
 - ii. Set memory map data widths to match AXI Interconnect requirements. Suggest stream data width x 4.
 - iii. Set maximum burst size. Suggest 256 for maximum throughput. (See the AXI Reference Guide UG761 for more information on maximizing the AXI Interconnect performance.)

- iv. Line Buffer Depth. (Suggest next power of two greater than maximum burst size x 6.)
- 2. Configure the write registers as Genlock master.
 - a. Set S2MM_DMACR (30h) to 0x00000003. This enables run/stop and Circular_Park.
 - b. Set S2MM_Start_Address 1 (ACh) through S2MM_Start_AddressN to their required locations. These locations can be static (based on maximum frame size) or dynamic (based on actual frame size).
 - c. Set S2MM_FRMDLY_STRIDE (A8h) to the appropriate value. FRMDLY is 0 for the Genlock master. STRIDE is the number of bytes per line.
 - d. Set S2MM_HSIZE (A4h) to the number of bytes per line.
 - e. Set S2MM_VSIZE (A0h) to the number of lines per frame. VSIZE must be set last and starts the S2MM VDMA transactions.
- 3. Configure the read registers as Genlock slave.
 - a. Set MM2S_DMACR (00h) to 0x000000B. This enables run/stop, Circular_Park, and SyncEn (Genlock).
 - b. Set MM2S_Start_Address1 (5Ch) through MM2S_Start_AddressN to their required locations. These locations should match their S2MM_Start_Address counterparts.
 - c. Set MM2S_FRMDLY_STRIDE (58h) to the appropriate value. FRMDLY is 1 for the Genlock slave. STRIDE is the number of bytes per line.
 - d. Set MM2S_HSIZE (54h) to the number of bytes per line.
 - e. Set MM2S_VSIZE (50h) to the number of lines per frame. VSIZE must be set last and starts the MM2S VDMA transactions.

When changing frame sizes, the incoming frame size may not match the S2MM HSIZE and VSIZE registers and an error is noted on S2MM DMASR register DMAIntErr. The preceding example disables S2MM Frame Advancement on Error and the next frame is written to the same frame store location invalidating the bad frame. If the start addresses are based on maximum frame sizes, no changes are necessary to their registers. However, the S2MM HSIZE and VSIZE registers must be updated with the new frame size. VSIZE should be written last. After a full frame is written into memory, the MM2S HSIZE and VSIZE registers can be updated and are used with the new frame after Frame Sync occurs.

Chapter 5

Constraining the Core

In synchronous mode, C_PRMRY_IS_ACLK_ASYNC = 0, all clocks run at the same frequency and are derived from the same source. There are no multi cycle or false paths in this design. All logic between flop-to-flop should meet timing within one clock period.

In asynchronous mode, C_PRMRY_IS_ACLK_ASYNC = 1, all clocks are treated asynchronously to each other and the core will write out appropriate clock domain crossing constraints.

Chapter 6

Detailed Example Design

There are examples in <u>XAPP739</u> and <u>XAPP740</u>.

Technical Support

Xilinx provides technical support at <u>www.xilinx.com/support</u> for this LogiCORETM IP product when used as described in the product documentation. Xilinx cannot guarantee timing, functionality, or support of product if implemented in devices that are not defined in the documentation, if customized beyond that allowed in the product documentation, or if changes are made to any section of the design labeled DO NOT MODIFY.

See the IP Release Notes Guide (XTP025) for more information on this core. For each core, there is a master Answer Record that contains the Release Notes and Known Issues list for the core being used. The following information is listed for each version of the core:

- New Features
- Resolved Issues
- Known Issues

Ordering Information

This Xilinx® LogiCORE IP module is provided at no additional cost with the standard Xilinx ISE® Design Suite Suite and ISE Embedded Edition (EDK) software under the terms of the Xilinx End User License.

Information about this and other Xilinx LogiCORE IP modules is available at the <u>Xilinx</u> <u>Intellectual Property</u> page. For information on pricing and availability of other Xilinx LogiCORE IP modules and software, contact your <u>local Xilinx sales representative</u>.

Revision History

Date	Version	Revision
10/19/11	1.0	Initial Xilinx release.
01/18/12	1.1	Summary of Major Core Changes
		Added 32 Frame Stores support
		Added Internal Genlock support
		 Added Frame Sync on TUSER0 support
		 Added additional stream data width support
		Summary of Major Documentation Changes
		• Removed List of Acronym from Appendix. For the first occurrence of each acronym, spelled out full text.
		• Added supported software drivers to IP Facts table.
		Created new section Scatter Gather Mode.
		• Reordered the hierarchy of the Register Space section.
		• Reordered the hierarchy of the Designing with the Core section.
		• Added the new section, Triple Frame Buffer Example.
		 Added new Appendix, HBlank and VBlank Periods for Standard Frames

The following table shows the revision history for this document.
